The American Psychological Association, founded in 1892 and incorporated in 1925, is the major psychological organization in the United States. The purpose of the APA is to advance psychology as a science, and as a means of promoting human welfare. It attempts to accomplish these objectives by holding annual meetings, publishing psychological journals, and working toward improved standards for psychological training and service.

In addition to the *American Psychologist*, the Association publishes 13 other journals: *Contemporary Psychology*, *Developmental Psychology*, *Journal of Abnormal Psychology*, *Journal of Applied Psychology*, *Journal of Comparative and Physiological Psychology*, *Journal of Consulting and Clinical Psychology*, *Journal of Counseling Psychology*, *Journal of Educational Psychology*, *Journal of Experimental Psychology*, *Journal of Personality and Social Psychology*, *Professional Psychology*, *Psychological Bulletin*, and *Psychological Review*. The APA also publishes *Psychological Abstracts*, the *APA Monitor*, a monthly *Employment Bulletin*, the *Biographical Directory*, the *Convention Proceedings*, the *Convention Program*, and the *Catalog of Selected Documents in Psychology*.

Racial and Ethnic Bias in Psychological Tests

Divergent Implications of Two Definitions of Test Bias

FRANK L. SCHMIDT *Michigan State University*¹

JOHN E. HUNTER *Michigan State University*

In recent years, the question of possible ethnic and racial bias in psychological tests has occupied a great deal of the attention of psychologists concerned with educational and employment testing. In this connection, agreement on the definition of test bias was necessary before meaningful research—or even meaningful discussions—could be carried out. Very early in this effort, agreement was reached that the position which defines a test as fair only if there are no mean score differences between population subgroups was untenable (Cleary, 1968; Guion, 1966). Such a definition eliminates a priori any possibility of real group differences on various psychological traits, a position which is more than questionable in light of empirical evidence indicating the widespread existence of such differences (Tyler, 1965). The definition that came to be accepted by most working in this area was the one given by Cleary (1968):

A test is biased for members of a subgroup of the population if, in the prediction of a criterion for which the test was designed, consistent nonzero errors of prediction are made for members of the subgroup. In other words, the test is biased if the criterion score predicted from the common regression line is consistently too high or too low for members of the subgroup. With this definition of bias, there may be a connotation of "unfair," particularly if the use of the test produces a prediction that is too low. If the test is used for selection, members of a subgroup may be rejected when they were capable of adequate performance [p. 115].

This definition of unfair test bias has been endorsed and advocated by educational researchers (Kallingal, 1971; Linn & Werts, 1971; Pfeifer & Sedlacek, 1971; Stanley & Porter, 1967), industrial psychologists concerned with selection (Bartlett & O'Leary, 1969; Einhorn & Bass, 1971; Grant & Bray, 1970; Tenopir, 1967), and textbook authors (Anastasi, 1968, p. 559; Cronbach, 1970, pp. 305–306). Even psychologists as highly critical of current testing practices as

Kirkpatrick (1970) have endorsed the Cleary definition (Kirkpatrick, Ewen, Barrett, & Katzell, 1968, p. 7). A detailed treatment of the statistical and psychometric requirements of this definition (Pott-hoff, 1966) has been written and has received wide acceptance and usage by researchers in this area.

More recently, an alternative definition of test bias has been advanced by Thorndike (1971). Thorndike's definition holds that a test used for educational or employment selection is fair only if, for any given criterion of success, the test admits or selects the same proportion of minority applicants that would be admitted or selected by selection on the criterion itself or on a perfectly valid test. For example, if it is known, based on past experience, that 37% of minority applicants equal or exceed the average majority group member in actual performance on the job or in the educational institution, and if the selection ratio is such as to admit 50% of the majority applicants, the test must admit 37% of the minority applicants to be considered fair.

Both the Cleary and the Thorndike definitions have a ring of reasonableness about them. Certainly, given acceptance of the principle of individualized treatment based on individual merit, it appears unfair to overpredict or underpredict the performance of any individual or group of individuals (Cleary's definition); likewise, it seems unfair to accept onto the job or into the educational institution a smaller proportion of any population subgroup than could in fact meet the criterion or criteria of success as set by the organization. In fact, it may appear that these two concepts of test fairness are conceptually equivalent—merely different ways of stating the same principle. This is not the case, however; the two definitions are very different, and in most testing situations, they lead to different conclusions about the fairness of a given psychological test. In this article, the two competing definitions of test fairness and their differing impli-

Figure 1. Prediction of black and white criterion scores from the white regression equation when $\epsilon X_W - \epsilon X_B = \epsilon Y_W - \epsilon Y_B = 1SD_x = 1SD_y = 10$. $\epsilon \hat{Y}_W - \epsilon \hat{Y}_B = 1SD_{\hat{Y}}$.

cations are explained and illustrated.³ In addition, data from a number of published studies on test bias are examined in light of these definitions.

It should be pointed out that the concern here is with the test bias, not with differential validity. When a test is not related to the criterion of interest within a population subgroup (i.e., has zero validity for the subgroup), there is no justification for its use with that subgroup. Of course, if such a test is used, it may, under certain circumstances, result in unfair discrimination against one or more population subgroups (Bartlett & O'Leary, 1969). The concern in the present article, however, is with unfair bias

³ A third concept of test bias, Definition 3 of Darlington (1971), is not examined in this article. This definition holds that a test is fair only when $r_{ex,y} = 0$ (where e = ethnic group membership, x = test score, and y = the criterion measure). It is stated in terms of a partial r in which the variable partialled out is (or should be) assessed at a point later in time than the other two variables. Thus, it is very difficult to assess the quality of this definition in reference to the usual and most plausible assumptions about the causal relations among the variables of ethnic group membership, ability, and performance, all of which would be stated in terms of later performance being caused by earlier variables of ability, ethnic group membership, etc. Probably because of this conceptual problem, this definition has received little attention in the research literature. (The conceptual problems associated with Definition 3 will be explored more fully in a subsequent paper by the same authors.) Darlington's (1971) Definitions 1 and 2 correspond to the Cleary and Thorndike definitions, respectively. Darlington's Definition 4 corresponds to the stipulation (discussed above) that a test is fair only if it shows no mean score differences between population subgroups.

that may exist in tests that are approximately equally valid for both majority and minority groups. Approximately equal validity for psychological tests within population subgroups appears to be the general rule. A recent study (Schmidt, Berner, & Hunter, 1973) has shown that when differences between the races in sample sizes used are taken into account, the frequency with which employment tests are reported in the literature to be valid for one race but not the other is no greater than would be expected on the basis of chance alone. It is likely that a similar situation obtains in the educational setting (Anastasi, 1968, pp. 561-562; Stanley, 1971). Tests equally valid for blacks and whites are equally successful in properly rank ordering individuals within both races on future criterion performance; however, they may be unfairly biased in that they place one race as a group too high or too low relative to the other.³

Closer Examination of Cleary and Thorndike Definitions

Consider the test-criterion relationship shown in Figure 1. X is a test used to predict a criterion variable, Y . Values of Y predicted from a regression equation are symbolized \hat{Y} . The symbols r_{xy} and SD will be used for both population and sample values, although discussion is essentially in terms of relations existing in the population. In order to simplify the presentation, the following assumptions are made: r_{xy} and marginal SDs (SD_x and SD_y) are assumed equal within and between cultural groups; conditional SDs of the criterion ($SD_{y,x}$) are assumed equal between cultural groups and within each group across levels of X . These assumptions imply equal regression slopes in each subgroup.⁴ The criterion

³ It should perhaps be noted here that the much-publicized U.S. Supreme Court ruling (*Griggs v. Duke Power*, 1971) concerning employment tests was directed to the issue of test validity, not test bias. The effect of the ruling was to uphold the legality of the Equal Employment Opportunity Commission (EEOC) requirement that tests or other selection devices on which minorities average below the white majority be shown to be related to job performance. EEOC guidelines (U.S. EEOC, 1970) require that, where feasible, such validity be demonstrated separately for both majority and minority groups. The guidelines devote only a few lines to test bias per se. Although the treatment is somewhat unclear, unfair bias appears to be defined in terms of Cleary's (1968) concepts.

⁴ Working under these assumptions precludes examination of unfair biases that might result from differences between groups in regression slopes, marginal and conditional variances, validities, or any combination of these factors. Possible effects of differences of this sort have been discussed elsewhere (Bartlett & O'Leary, 1969; Einhorn & Bass, 1971).

measure is assumed to be free of unfair bias and contamination,⁵ and the joint distribution of X and Y is assumed to be bivariate normal in each cultural group. It is also assumed that $r_{xy} > 0$, because there is little point in discussing the cultural fairness of an invalid test.

In discussing Figure 1, the subscript W (for white) will be used to designate the majority group and B (for black) to designate the minority group.⁶ Assume, then, $SD_{xw} = SD_{xb} = SD_{yw} = SD_{yb} = 10$. Although not shown, the black mean on Y in our illustration falls one standard deviation below the white mean, just as is the case on X , that is, $\epsilon Y_B = 40$ and $\epsilon Y_W = 50$ (where ϵ symbolizes the operation of taking the mean). If $r_{xy} = .50$, the white regression equation is $\hat{Y}_W = .50X + 25$. Now, $\epsilon Y_W = \epsilon \hat{Y}_W = 50$, by definition, but $\epsilon Y_B = 40 < \epsilon \hat{Y}_B = 45$. Thus, this test predicts an average criterion performance score of 45 for blacks, when in fact the average score earned by blacks is only 40. According to Cleary's definition, then, the test shown in Figure 1 is biased; it systematically overpredicts the criterion scores of blacks. But it can be seen that the position of the minority group relative to the majority group is the same on \hat{Y} as on X and Y . Approximately 16% of the minority group is above the majority mean on X , Y , and \hat{Y} , despite the overprediction of black criterion scores. This obtains because $SD_{\hat{Y}} = .50SD_x$ ($SD_{\hat{Y}} = \beta SD_x$). The overprediction of black criterion scores is "compensated for" by the reduction in SD that occurs as we move from X to \hat{Y} . Despite the overprediction, then, a black with a given standing in the white X distribution, say the 50th percentile, will have that same standing on \hat{Y} . According to Thorndike's definition, this test is therefore unbiased because it assigns the same *relative standing* to the two groups on \hat{Y} as they have on the criterion measure itself. If the selection ratio were such that all applicants scoring at or above the white mean (50 or above) were selected, approximately 50% of the white and 16% of the

TABLE 1

Percentage of Minority Group Applicants Accepted under Different Selection Criteria

Selection ratio	Criterion (Y)	Cleary \hat{Y}	Thorndikean \hat{Y}
Top one sixth	3.14	.22	3.14
Top one third	9.68	1.19	9.68
Top one half	19.77	3.12	19.77
Top two thirds	34.83	10.93	34.83

Note. Percentage of minority in applicant pool = 20%.

black applicants would be selected—exactly the same percentage of each group that would in fact be above the white mean on the criterion, that is, on actual performance. Thus it can be seen that Thorndike's concept of test fairness leads to the paradoxical conclusion that in order to be fair, a valid test used for selection or admissions purposes must overpredict the actual criterion scores of members of population subgroups with lower mean criterion scores.

On the other hand, if one follows Cleary's definition and considers the test depicted in Figure 1 to be biased, he would make use of the test "fair" by computing and using a separate regression equation for blacks. The intercept for this equation would be 20 and $\epsilon \hat{Y}_B = \epsilon Y_B = 40$; that is, the equation would neither underpredict nor overpredict for blacks. Figure 2 shows that when separate minority and majority regression equations are used with the test depicted in Figure 1, $\epsilon \hat{Y}_W - \epsilon \hat{Y}_B = 2SD_{\hat{Y}}$ rather than $1SD_{\hat{Y}}$ ($SD_{\hat{Y}}$ remains unchanged at 5), and thus only about 2.3% of the minority group members reach or exceed $\epsilon \hat{Y}_W$. If one could select on the criterion itself (or on a perfectly valid test), and if the cutoff score were ϵY_W , approximately 16% of the minority group members would be selected. Use of test X with separate regression equations results in the selection of only 2.3% of the minority applicants. The dramatically different implications of the Cleary and Thorndike definitions can be seen in Table 1. For all selection ratios, selection on the basis of a test meeting Cleary's definition of fairness results in the acceptance of a markedly smaller percentage of minority applicants than selection on a test meeting Thorndike's definition. Thus these two concepts of test fairness can not only lead to opposite conclusions about the fairness of a given test usage, they can also have very different practical implications.

Holding the differences between the groups on the criterion constant, the larger the validity coefficient, r_{xy} , the smaller is the overprediction of black cri-

⁵ As has been pointed out repeatedly (Cleary, 1968; Guion, 1966; Thorndike, 1971), if the criterion measure is unfairly biased to an unknown degree and in unknown directions, no meaningful analysis of test fairness is possible. For this reason—and for others more obvious—great care should be taken to insure that racial or ethnic prejudice or favoritism do not contaminate performance evaluations made of individuals. Although this may be difficult in certain situations, it is not impossible (e.g., see Grant & Bray, 1971).

⁶ Obviously blacks are not the only minority group showing a tendency to score below the white mean on psychological tests. Symbols used here were chosen for convenience and because the bulk of the published research in this area has focused on black-white comparisons.

terion scores necessary to meet the requirements of the Thorndike definition. When validity is 1.00 for both groups, no overprediction is necessary, and Thorndike's definition of test bias becomes identical to the Cleary definition. Holding test validity constant, the smaller the between-groups difference on the criterion, the smaller the overprediction of black criterion scores necessary to meet Thorndike's definition. When the two groups do not differ on criterion performance, no overprediction is necessary, and the Thorndike and Cleary definitions are once again identical. Table 2 perhaps clarifies these distinctions somewhat. In three of the four quadrants, the two definitions are identical, but two of these three essentially do not occur in reality; there are no known reports of tests with perfect validity. The situation in which there are no subgroup differences in criterion performance occurs with some degree of frequency, especially in employment settings (Kirkpatrick et al., 1968; Lopez, 1966; Rhode, 1971). But the situation in which test validity is less than perfect and in which there exists a between-groups difference in criterion performance is probably the most common, especially in educational institutions (Anastasi, 1968, pp. 561-562; Cronbach, 1970, pp. 302-307). The Cleary and Thorndike definitions of test fairness will therefore usually be in conflict.

Reanalysis of Published Data

Most research on the question of test fairness has been based on the Cleary definition and, whether carried out in employment or educational settings, has found a tendency for regression equations developed on white or combined samples to overpredict the actual criterion performance of blacks. In the educational setting, the best known and most quoted of these studies is that of Cleary (1968) herself. Using Scholastic Aptitude Test Verbal and Quanti-

tative scores as predictors, she compared actual and predicted grades of black and white students attending three integrated colleges. In all three of these colleges, actual grades of blacks were lower than predicted grades, and this difference was significant in one of the colleges. Temp (1971) found that the grades of blacks were overpredicted, in varying degree, by the regression equation developed on whites in 12 of the 13 colleges he studied. Other educational studies have reported similar results (Kallingal, 1971; Pfiefer & Sedlacek, 1971; Wilson, 1969). Similar findings have been reported for the employment setting (Campbell, Pike, & Flaughner, 1969; Gael & Grant, 1972; Grant & Bray, 1970; Guinn, Tupes, & Alley, 1970; Tenopyr, 1967). Following Cleary's definition, these researchers have almost invariably concluded that the tests and regression equations investigated were either fair to both races or were biased significantly in favor of blacks. But, as seen above, a test meeting Thorndike's definition of fairness will of necessity show overprediction of minority criterion scores in most situations.⁷

With this consideration in mind, data from two educational (Cleary, 1968; Temp, 1971) and two employment (Gael & Grant, 1972; Guinn et al., 1970) studies were reanalyzed using the criterion of fairness proposed by Thorndike.

Assuming normal distributions for both population subgroups on Y and \hat{Y} , Thorndike's definition requires that the standard score in the Y_B distribution corresponding to ϵY_W be equal to the corresponding standard score in the \hat{Y}_B distribution for $\epsilon \hat{Y}_W$. Given ϵY_B , SD_{Y_B} , and ϵY_W , the standard score in the Y_B distribution corresponding to the ϵY_W was computed, and the percentage of minority group members falling above this score was obtained from an ordinary normal curve table. Using $\epsilon \hat{Y}_B$, $SD_{\hat{Y}_B}$, and $\epsilon \hat{Y}_W$, the same thing was done for the \hat{Y} distribution.⁸ (All \hat{Y} s were, of course, those produced using the white-derived regression

⁷ Significantly, the three studies that reported findings of unfair bias against lower scoring minority groups did not work from Cleary's concept of bias (Kirkpatrick et al., 1968; Lopez, 1966; Rhode, 1971). In these studies, the quantities $\epsilon Y_W - \epsilon Y_B$ and $\epsilon X_W - \epsilon X_B$ were compared by simple observation or with respect to differential statistical significance. These procedures are equivalent to application of the Thorndikean concept of test fairness.

⁸ $SD_{\hat{Y}_B} = r_{xy}$ (or the multiple correlation coefficient) times SD_{Y_B} . Where r_{xy} or the multiple r was not given, as in Cleary's data, $SD_{\hat{Y}_B}$ was computed as $B'C_{xx}B$, where B = the majority equation regression weights and C_{xx} = the test variance-covariance matrix for the minority group.

equation.) Then for each test, the difference between these two percentages was tested for significance. The Thorndikean test for unfair bias can thus be seen to be quite simple and straightforward.

It can be seen in Table 3 that in all three of the colleges studied by Cleary, the percentage of blacks above the white mean on \hat{Y} was significantly smaller than the percentage above the white mean on Y . This discrepancy was as great or greater for Colleges 1 and 2 as for College 3, though College 3 was the only college in which the overprediction of black grades was statistically significant. The results are similar for the data from Temp's (1971) study. In 12 of the 13 colleges he studied, the trend, according to the Thorndike definition, was in the direction of unfair bias against black students, and in 8 of the colleges this effect reached statistical significance. This occurred despite the fact that in 10 of the 13 colleges, actual black grades were significantly overpredicted. In both studies, the white regression equation was overpredicting for blacks but not to a great enough extent to make the tests fair under the Thorndike definition.

It can be seen in Figure 1 that when the white equation is applied to both groups, percentage of overlap on \hat{Y} is identical to that on the test or test composite. Thus, the source of "unfair bias" is to be found in the tests themselves; it is not an artifact of the regression technique. The last two columns in Table 3 present the Thorndikean bias analysis for the actual predictors used in the Cleary (1968) and Temp (1971) studies, the verbal and quantitative sections of the well-known Scholastic Aptitude Test. The general trend is for the tests themselves to be somewhat less biased than the \hat{Y}

composite,⁹ but in every case the difference between overlap on *Y* and on *X* was in the direction of Thorndikean bias against black students. In 17 of the 32 comparisons, this effect reached significance.

In the two employment studies, results were similar. Guinn et al. (1970) used various Air Force Aptitude Indices as single tests in the prediction of final grades for white and black airmen in each of 10 technical training courses. Black grades were overpredicted in all 10 technical areas, and the overprediction was statistically significant in 3 of the groups. But, as can be seen in Table 4, there was nevertheless a trend toward unfair bias against blacks in the Thorndikean sense in each of the 10 technical areas, and in 6 of the areas this effect reached significance. Thorndikean bias was not invariably less in the technical areas showing significant overprediction of black grades than in the other areas. Also shown in Table 4 are results from the Gael and Grant (1972) study. Each of the four regression equations presented for this study contains a single predictor, and all equations are those derived on the white subgroup.^{10,11} The performance criterion was a carefully developed composite of a job knowledge test and several job sample measures. In each case, the white regression equation overpredicts black criterion scores, but the first and second equations are nevertheless significantly biased against blacks according to the Thorndike definition. Equation 3 shows no significant bias, and the fourth equation is significantly biased in favor of blacks.

The Two Definitions: Practical Implications

Obviously, then, the two definitions of test bias can and do lead to very different conclusions about the fairness of tests used in everyday life to make decisions about people. Adoption of the Cleary definition leads to the conclusion that many educa-

tional and employment tests, as used, are probably either fair to, or biased in favor of, lower scoring minority groups; acceptance of the Thorndike definition, on the other hand, means that many currently accepted test usages are probably unfair to such minority groups.

But there are implications beyond this one. The Cleary definition is based on the principle of least squares estimation of criterion scores; as such, it insures that the average performance level of selectees will be maximized. College students, workers, or management trainees selected under the Cleary definition will, on the average, show higher levels of performance than those selected using the Thorndike definition. There can be little doubt that the maximization of the individual-occupational role fit which results from application of the Cleary definition is of great benefit to the individual in terms of his educational and occupational success and satisfaction in life and to society in terms of performance maximization, not only of individuals but also of social institutions as institutions. Simple statistical principles can be used to demonstrate that adoption of Thorndike's definition of test fairness leads to a greater incidence of placement of individuals in educational and occupational roles for which they are unsuited psychologically. Conversely, use of the Thorndike definition means that certain majority applicants will be rejected in favor of minority applicants with lower statistical probabilities of success on the criterion—a situation that would be considered reverse discrimination by many.

There is a final practical problem associated with the use of the Thorndike definition. Thorndike's definition is based essentially on probability matching; it states that, for a given definition of adequate or successful performance, the proportions of the minority and majority subgroups chosen should correspond to the probabilities of success for individuals drawn at random from each of the groups. If lower scoring ethnic groups other than blacks, Chicanos, Indians, etc., were to demand these same probability matching privileges for themselves, and if probability matching were imposed on higher scoring and performing ethnic and social groups (where it would reduce chances of selection or admission), much if not most of the societal benefit accruing from the use of valid selection procedures would be lost. In fact, if lower scoring members of the majority group defined themselves as a group and demanded and received probability matching privileges, differential selection and placement would become a virtual impossibility. For example, consider again

⁹ \bar{Y} is a composite of both tests and therefore somewhat more reliable than either test taken individually. Linn and Werts (1971) have shown that, under these circumstances, overlap of two distributions with dissimilar means will be smaller for the more reliable measure.

¹⁰ It should be apparent from the previous analysis that degree of Thorndikean bias against blacks would have been even greater had the black-derived regression equation been used to predict for blacks and the white-derived equation used for whites. The prediction situation would then have been similar to that shown in Figure 2 instead of Figure 1.

¹¹ The predictor in the first equation is the raw score sum of the two most valid tests. Equations 2, 3, and 4 were not presented as such in the study; they were calculated from information given.

the situation illustrated in Figure 1—in which the test is fair to the minority group under Thorndike's definition and the minimum score for selection is 50. There is nothing to prevent majority group members who score below 50 from maintaining that the test is unfair since the percentage of their group selected (0%) is less than the percentage that would in fact be successful if all in their group were selected (33%).

On the other hand, in many situations, application of the Cleary definition means that the probability of acceptance for minority group individuals is reduced essentially to zero. When validity, though statistically significant, is relatively low and when the difference on the criterion favors the majority group, the Cleary definition is particularly disadvantageous to minority groups. Figure 2 can be used to illustrate a situation of this sort. The reader is asked to consider the effect of lowering the validity of the test shown in Figure 2 from .50 to .30. The new regression equations become $\hat{Y}_W = .30X + 35$ for whites and $\hat{Y}_B = .30X + 28$ for blacks. $SD_{\hat{Y}}$ is now 3.0 instead of 5.0, and the white and black means on \hat{Y} are now separated by 3.33 instead of $2.00SD_{\hat{Y}}$. Under these circumstances, if the white mean on \hat{Y} (i.e., predicted criterion performance of 50) were once again used as the selection cutoff score, the probability of being selected or admitted for minority group members would be less than .0005.¹³ Stated another way, whenever performance differences favor the majority group, the lower scoring minority group as a group is disadvantaged in inverse proportion to the validity of the test—a situation that might plausibly be argued to be unfair.

Although both concepts of test fairness have advantages, the disadvantages of each are perhaps more obvious. It might appear, then, that the best solution would simply be the elimination of educational

Figure 2. Prediction of black and white criterion scores with separate regression equations when $\epsilon X_W - \epsilon X_B = \epsilon Y_W - \epsilon Y_B = 1SD_{\epsilon} = 1SD_{\epsilon} = 10$. $\epsilon \hat{Y}_W - \epsilon \hat{Y}_B = 2SD_{\hat{Y}}$.

and employment selection and placement tests. This solution, however, is no solution at all. Whether tests are used or not, decisions must be made about people. A given college must decide which applicants will be admitted and which will not; usually not all can be admitted. A personnel director must decide who will be hired onto a specific job and who will be rejected; typically there are more applicants than positions. If tests are not used as aids in making these necessary decisions, then other devices—such as the interview, letters of reference, and subjective hunch—must be heavily weighted. The record of validity for such procedures is a poor one relative to that of psychological tests (Anastasi, 1968; Ghiselli, 1966; Mosel & Goheen, 1958; Ulrich & Trumbo, 1965). But more important for the present discussion is the fact that these procedures—and other alternative procedures—are characterized by the same problems of potential unfair bias discussed above in relation to tests. In the selection setting, there is no essential conceptual or practical distinction that can be drawn between test scores and scores or ratings produced, for example, by the interview. Both are potentially susceptible to biases of various kinds, the interview perhaps more so than the typical psychological test (Anastasi, 1968, p. 563; APA Task Force on Employment Testing, 1969). Obviously, then, assessments of applicants produced by the interview, references, and similar procedures can and should be analyzed for unfair

¹³ Although separate regression equations will usually be theoretically appropriate under Cleary's definition, it should be noted that the existence and use of a separate (lower) equation for the minority group is not a necessary condition for this effect. For example, if test validity were .30, mean black criterion performance (ϵY_B) were 41 and mean black test performance (ϵX_B) were 20, then (with all standard deviations again equal to 10 and mean white performance on both test and criterion again at 50) the regression equation $\hat{Y} = .30X + 35$ would be appropriate for both races. Because it would neither underpredict nor overpredict for either race, the test (used with a single regression equation or in raw score form) is unbiased according to the Cleary definition. But while 18.4% of blacks would be above the white mean on actual performance (Y), less than 1% would be above the mean on predicted performance (\hat{Y}).

racial and ethnic bias.¹³ And in order to do this, there must be some agreement as to what constitutes unfair bias. Of course, the problem can be covered over and concealed by deliberately keeping all assessments, both of performance capability and of actual performance, in unquantified form. But it should be obvious that obscuring the problem does not eliminate or solve it.¹⁴

There appears to be no real alternative to a serious and intelligent consideration of the relative merits of different definitions of selection fairness.

¹³ In this connection, it should be noted that EEOC validation requirements are not limited to tests; the same evidence of practical validity required for tests is required for nontest procedures such as the interview, references, etc.
¹⁴ Such assessments must be put into quantitative form, however crudely, in order to meet EEOC validation requirements. (See Footnote 13.)

The Politics of Empiricism

Research Recommendations of the Joint Commission on Mental Health of Children

NORMAN H. HAMM *University of Nebraska at Omaha*¹

The final report of the Joint Commission on Mental Health of Children (1970) is a provocative social mandate for America's children, calling for a general reorganization of the child mental health enterprise around *prevention* rather than the traditional *treatment* of mental disorders once they occur. Accordingly, a fourfold approach is forcefully presented: (a) the development and implementation of a child advocacy system; (b) a comprehensive health, support, and remedial care system for children, particularly for the socially disadvantaged; (c) expanded, individually based, applied and basic research on child mental health; and (d) new approaches to the development of mental health manpower. Additional chapter summaries deal with aspects of poverty, racism, employment, education, and the relation of these aspects to child mental health.

While the four general recommendations are obviously interrelated and difficult to separate, this article will critically examine the efficacy, training, and administration of research in terms of meeting the goal of children's mental health.

The author's method is limited, if not indeed somewhat paradoxical. What is offered is a *rational analysis* of our empirical enterprise as it applies to practical payoff, especially mental health. What surely is needed is a science of science (not to be confused with a philosophy of science), or research performed on research policy; however, in the profound absence of such knowledge, one can only guess and offer hypotheses about which principles will produce the most scientific progress.

The Efficacy of Research on Child Mental Health

Although the report places no monetary value on any of its recommendations, research is one of the four major areas with which it deals. The Commission recommends increased support of both pure and applied research together with the establishment of 10 child mental health research centers under the auspices of the National Institute of Mental Health or the National Institute of Child Health and Human Development. Such a conceptual, if not monetary, acknowledgment presumes that scientific research can have a major impact on children's mental health. Such an assumption is clearly an important one, particularly for a preventive approach to mental health.

An analysis of presumed research payoff has two levels, one fairly simple and the other quite complex. Regarding the former, adequate evidence already exists regarding the variables, particularly early experiences, that greatly influence mental health. At the present time, a psychological prescription could be written during childhood which would minimize the causes of mental illness later in life. Knowledge of proper environmental dosages may not be as exact as in the practice of internal medicine, but they nevertheless exist. Additional research of the type recommended in the Commission's report would undoubtedly add greatly to the precision of mental health prescription.

The assumption becomes inexorably complex when consideration is given to whether society will use such information in a preventive manner. While the actual choice of therapeutic procedures may be made on a personal moral basis instead of an empirical one (see Baer, 1970; Johnston, 1972; Solomon, 1964), mental health practitioners would probably implement new knowledge as it becomes available. Their professional consciences would

¹Requests for reprints should be sent to Norman H. Hamm, Department of Psychology, University of Nebraska, P.O. Box 688, Omaha, Nebraska 68101.

probably dictate change. In the case of the lay public, however, knowledge concerning mental health may continue to be largely unused. The question is whether the public will use the results of sound behavioral research.

Some evidence exists on both sides. Many influential individuals, including the Vice-President of the United States, have deplored the creeping influence of the behavioral scientist and engineer into contemporary life. The loss of autonomy, resistance to a deterministic view of life, and the increasing predictability of behavior do not appeal to large segments of the lay public. In addition, the argument commonly used against B. F. Skinner's *Walden Two* concerns the totalitarian organization of the community, with behavioral engineers, instead of politicians, on the top of the social pyramid.

If the prescription for child mental health were written on the national level, it is somewhat doubtful whether a substantial number of parents would follow it. The real negative consequences of inadequate child rearing have little impact on the family until adolescence and adulthood. Moreover, a substantial number of parents are emotionally incapable of providing the nurturance necessary for the mental health of their children. They have too many of their own problems with which to contend.

Nevertheless, there is some reason for optimism. The strategy of childhood prevention made possible by increased research has the potential of largely eliminating our generally nonproductive psychiatric population. The logic is appealing, if not the actual dollar consequences.

Some signs point to the increasing social usage of research findings. The recent social legislation concerning the advertising of cigarettes and also the limiting of violence in children's cartoons demonstrate that some social action is already possible; both involved substantial policy changes based on the findings of scientific research, the former from medicine and the latter from psychology. Not all research results may be translated into governmental policy, however. It is likely that the results of empirical research will have little social impact when they conflict with social taboos such as the recent report of the Commission on Sex and Pornography. The scientific evidence unfortunately conflicted with society's prejudices.

The willingness of the public to support and use the information gathered by extensive and expensive research on child mental health has yet to be

firmly established. Before larger sums of money are spent on research, the public must be consulted. After all, it is the taxpayer who must pay the price, while we professionals earn our keep. Under such circumstances, it is difficult to be objective. As a profession, we must guard against the tendency to impose our cherished values on the nonprofessional public. It may be hoped that the advocacy portion of the Commission's recommendations will effectively present the case for children's rights and mental health. Once these rights are accepted by society, then professionals can duly serve as the technical experts necessary to meet their implementation.

Research Policy and Administration

After the absolute amount of dollars is assigned to research concerned with human development, important questions arise concerning research policy and implementation. The overall question is which set of policies offers the most preventive payoff. On this point the Commission takes a strong, but disappointingly, traditional stand.

Except for the recommendation concerning the establishment of 10 child mental health research centers throughout the country, most of the Commission's recommendations support the research status quo. Briefly, both basic and applied research are necessary and should be increased; policy should maximize the "opportunities" and "productivity" of the individual researcher, especially as related to the university's role in basic research; appropriately designed applied research should be increased to assess social action programs; multidisciplinary collaboration is encouraged; and NIMH should sponsor, under its Clearinghouse function, more adequate information retrieval and dissemination to professionals. The last recommendation has been noted by others (Etzioni, 1972), and the Interagency Panel of Early Childhood Research, established in 1970, has begun to coordinate child development research of nine agencies under the Department of Health, Education, and Welfare. A similar interagency panel is being established for adolescence.

Below the level of policy, topical priority is given by the Commission to longitudinal, multivariate, life-span studies of human development, methodological research on child development and mental health, and specific studies dealing with early infantile autism, childhood schizophrenia, the natural

history of emotional disturbance, and the effectiveness of various intervention procedures on mental illness, institutionalization, and drug use. The latter studies are to be conducted in the 10 child mental health research centers.

Obviously, there is much that is right about the research policies and specific study areas recommended by the Commission. The specific study areas in particular are soundly conceived; they represent significant problem areas related to child mental health, and the methodological issues raised are premised on developmental research performed in the last several decades. At the principle level, however, the Commission does not go far enough in redirecting our national research policy.

The basic problem with current research administration is *accountability*. Increasingly, in recent years, I have become disenchanted with *individually* sponsored research within *university settings*. Several recent writers have noted the basic incompatibility between university settings and mission-oriented, interdisciplinary research (Harris, 1968; McElroy, 1971; Piel, 1969). While I have every reason not to be an iconoclast, speaking as a former graduate research assistant, predoctoral research fellow, and principal investigator myself, I feel compelled to kill the goose that laid the golden egg.

It is not that scholars should divest themselves of scholarship, but that governmental research institutes, either on or separate from university settings, might be scientifically more productive. The primary problem is that professors and students can be only part-time researchers. They both have other important duties. Professors have teaching, university administration, and community service to tend to, while maze-running, hurdle-jumping graduate students must give considerable (if not full) attention to their academic standing.

The counterargument is often posed that research activities complement and overlap professors' and students' other duties. This argument rings in the hallowed halls of academia today. The overlap, however, is imperfect, and no matter how talented the individuals, their nonresearch responsibilities can only subtract from the time available for the generation of new knowledge. It is still only in the providence of the renaissance man to make substantial contributions to all four areas: research, university administration, community service, and teaching.

The administratively wasteful policy of supporting part-time researchers is undoubtedly reflected in any cost-productivity analysis. To be sure, scientific research would be expensive under any set of policies. However, my experience indicates that the cost per published study is substantially increased by funding projects to individual, part-time researchers. Perhaps science cannot be conceived in terms of a cost-productivity analysis; indeed, some studies take considerable thought and time for execution and may significantly contribute to knowledge, but the business world should afford such extravagance! There are too many videotape recorders, slide projectors, research trailers, and voice keys accumulated by part-time researchers, which are used for few days or months a year—mine included.

Nothing short of drastic action is needed. In this regard, the advantages of centralization and full-time researchers recommend the European model of university- or non-university-related technical institutes. Certain of these institutes, like the 10 child mental health research centers recommended by the Commission, would deal with specific problem areas. Most would be mission oriented. All employees would be full time, but in recognition of the intimate relationship between higher education and research, a certain percentage would rotate between academia and the institutes. Instead of profit as a product, numbers of published articles, coupled with their scientific significance, would be given administrative consideration. Reinforcers such as salary, promotion, and administrative positions, would be contingent on the scientist's actual accomplishments. Finally, equipment usage would be recorded and policies of equipment sharing established among institutes, particularly regarding the most expensive pieces of apparatus.

In short, the present author would like to go beyond the recommendation of 10 child mental health research centers and substantially cut back on individually funded grants to mainly university personnel. The research dollar would likely be lengthened by the European technical institute concept together with accountable administrative procedures which reward individual scientists for productivity. In the end, however, an emerging body of empirical data concerning the efficacy of various research policies should buttress the administrative procedures of government agencies. What is needed is a science of science.

Research and the Professional Practitioner

As a former half-time exile from experimental child psychology, doing applied research for a social action agency within a university setting, I have lived in Cronbach's (1957) divided world of experimental and applied psychology. The internal dissonance produced by this schism might have produced some satisfying personal growth and interesting soliloquies, if the immediate emotional consequences of frustration and conflict could have been removed. My experiences have been totally politicizing.

Despite Cronbach's careful documentation, it is my belief that the schism in psychology exists today, but for a deeper reason. Cronbach's claim is that the research procedures used by experimentalists differ substantially from those employed by practitioners; the experimentalists stress the mean, group homogeneity, and analysis of variance, while the correlationists rely on the standard deviation, group heterogeneity, and factor analysis. Both, however, base the acquisition of new knowledge on scientific empiricism.

The conflict between pure and applied social science is simpler and more general: It is an epistemological conflict that profoundly affects both the professional practice and interpersonal relations of the applied scientist. At the expense of alienating my philosopher colleagues, in practice there are essentially two ways of knowing: *rationalism* and *empiricism*. Experience has taught me that mental health practitioners frequently rely on the former, while experimentalists rely on the latter method of knowing. In some cases, the applied practitioner's rational method may even lead to a reliance on intuition; the constraint of dissonance among internal elements is thereby removed. In short, the conflict between experimental and applied psychology is not so much between different research tools, but whether empiricism or rationalism is supreme as a way of knowing. Psychology is a science, while applied psychology is at best part science and part art. When the practitioner does rely on empiricism he adopts the research tools outlined by Cronbach.

There is a practical advantage to empiricism which totally transcends its epistemological nature: A reliance on empiricism minimizes the potential for individual and professional conflict in applied, particularly social action, settings. The reason for this is that it provides all professionals with an

objective means of evaluating the effectiveness of various policies, individuals, or programs. Evaluation is thereby taken out of the personal-political realm, and the emphasis is placed on the subject.

The consequences of an antiresearch bias on the part of practitioners are often tragic. With no objective means available for evaluation, many decisions regarding policy, individuals, or programs polarize the professional group and shift attention away from the children, placing it on staff relations. Staff morale sinks, work anxiety increases, certain key individuals resign, and the intervention program is doomed to failure. I have seen the pattern countless times and watched our valuable tax money wasted. An empirical orientation on the part of practitioners would not be a complete panacea, but the level of interaction among different professionals would undoubtedly be raised. The other alternative is to all become politicians.

The frequent reliance on rationalism by practitioners largely represents a failure of our professional training institutions. Students undoubtedly learn values along with their education. Many professional schools have either dropped or lessened their research requirements. If students have had adequate research training, they soon forget their research knowledge and retain only the skills that are used day to day. We need to not only bolster the research component of graduate education, but provide continued in-service training after graduation. Ideally, as recommended by the Commission, the professional staff should be continually involved in applied research and program evaluation. At the present time, huge sums of money are spent on social action with little knowledge concerning the effectiveness of the dollars budgeted.

A final note might be made of the Commission's child advocacy system, composed of neighborhood child development councils, local child development authorities, state-level child development agencies, and a national-level advisory council on children. This new consumer-professional coalition brings power to the people, involves nonprofessionals in child health programs, and, in general, increases the public's awareness of child mental health problems. This last factor in particular may do much to overcome the indifference toward child mental health noted in the first section. However, the dollar cost of such persuasion would be either prohibitive or better spent on the other recommendations concerning manpower training and child services.

The Future

In the end, it is hoped that changes in certain administrative procedures will do much to make up for America's decreased investment in research. During the early 1960s, America's expenditure for basic science increased by an impressive 16.2% per year (McElroy, 1971). However, the most recent federal growth rate is not large enough to even offset inflation.

Change is underway today. A research task force of the National Institute of Mental Health is engaged in a massive one-year review of the Institute's science activities. Ten study groups, composed of the Institute's major research interests, have been established. It is hoped that they will be successful in one of their principal objectives, the development of optimal administrative and organizational arrangements. What is needed is a coordinated program of research like that recently proposed for the environment (see Bowers, Hohenberg, Likens, Lynn, Nelkin, & Nelkin, 1971). As noted by McElroy (1971) and here, research policy, in all likelihood, will become more centralized,

mission oriented, interdisciplinary, and perhaps less university centered.

Editorship Nomination

The APA Publications and Communications Board invites nominations for the editorship of the *Journal of Counseling Psychology* for the term running 1976 through 1981. In order to provide a year of overlap with incumbent Ralph Berdie in 1975, the Board will appoint an editor-elect this year. Members wishing to suggest candidates should prepare a brief statement of one page or less in support of each nomination and mail no later than March 1, 1974, to Anita DeVivo, Executive Editor, APA Journals, 1200 Seventeenth Street, N.W., Washington, D.C. 20036.

Children and Public Policy

A Role for Psychologists

CRAIG T. RAMEY *University of North Carolina, Chapel Hill*¹

In 1970 the Joint Commission on Mental Health of Children published a report entitled *Crisis in Child Mental Health: Challenge for the 1970's*. The document is a plea for this country to reaffirm its concern for its young through meaningful actions and programs. The report was the product of three years of labor and the advice of "more than five hundred of the country's leading authorities on early childhood, adolescence and the young adult [p. iv]." Thirteen national professional associations, including the American Psychological Association, were represented on the Commission's Board of Directors.

The scope of the report reflects the diverse disciplines which were represented. Legal, medical, and educational reforms are advocated in an attempt to diminish the all too frequent occurrences of inequality of justice, care, and opportunity.

The report is a potential landmark in the establishment of adequate services to the children of this nation. Because many of the recommendations in it are controversial, it is desirable that the American Psychological Association, as an official body, recognize and respond to the various positions set forth. Individual psychologists are frequently called on by government and other public institutions to provide advice and counsel in matters concerning public policy for children. Yet, it is only rarely that psychologists seek to influence the course of public policy through actions by their professional associations.

By making a cohesive and collective response to this report we could make one of the most powerful responses that psychologists have yet made concerning formulation of public policy for children's programs.

The Commission's report advocates major reforms in areas such as physical and mental health services, employment, and education. Its major strength lies in its unflinching confrontation with many of the basic ills of our society, including disintegrating family life, injustice to minority groups, and lack of serious commitment to our children who are emotionally disturbed or mentally ill.

The report also has a weakness, albeit a very understandable one. The weakness is that in this attempt at comprehensiveness, priorities are not ordered, nor in many cases are specific mechanisms advocated to discover and to remedy the many deplorable life circumstances which affect our young. Although the members of the Commission are to be commended highly for their serious and difficult labor, the report would have been even stronger if such steps had been carried through.

In this article, two different issues are pursued. First, issues raised by the report are discussed and recommendations for APA's response are made. Second, a model is proposed which could be used to deliver many of the services that are advocated.

Responses to the Commission's Report

1. In developing positions on matters of public policy for children, APA should limit itself to those areas in which it can legitimately claim professional expertise. A guideline for this recommendation is that APA's official position regarding any public policy or program be limited to domains in which significant numbers of psychologists have made or are making direct professional contributions.

2. Before assuming an official position, the APA should conduct or make use of existing cost analyses for specific programs it feels to be legitimately within the domain of psychology. These analyses should include a careful delineation of manpower and facilities needed for effective implementation

¹ Requests for reprints should be sent to Craig Ramey, Frank Porter Graham Child Development Center, University of North Carolina, Chapel Hill, North Carolina 27514.

as well as our best estimates of the costs to society associated with not implementing the advocated program. This suggestion is not made casually. Rather, it is made with the full realization that such efforts are costly in both time and money. Nevertheless, if we are to advocate specific courses of action, then it is incumbent upon us to demonstrate the desirability and feasibility of particular programs. Such analyses will help to formulate policy and to avoid unnecessary and destructive criticism of being utopian in goals or naive to the process of implementation.

As a result of the information made available through the cost analyses and information on alternative programs, the APA national staff could begin to establish tentative priority statements. These statements could include expert opinion on the probability of funding during current administrations and other pertinent observations. This information might be made available to APA members by mail, and open forums could be held on these issues at national and regional meetings. Following these discussions, mailed ballots could be sent to the general membership to determine specific courses of action.

3. During the process of priority setting it serves no constructive purpose to make derogatory comparisons between funding in nonmental health sectors and mental health programs. For example, comparisons deprecating the cost associated with military programs, as is done in the Commission's report, are probably unwise and should be avoided. This course of action is recommended not because there is no legitimate debate over the government's overall funding priorities, but rather because mental health programs can be justified on their own terms. Further, official comparison with other agencies engenders a needless and, in all probability, unproductive competitive stance toward much more established and powerful lobbies.

4. After priorities have been set, resources should be made available to representatives of APA effectively to inform legislative leaders of our policy decisions. Specifically, APA should either choose lobbyists from its own ranks or retain competent individuals from outside the membership.

Responses to Specific Issues

PREVENTION OF PSYCHOPATHOLOGIES

The Commission's report was very clear in its recommendation that prevention of emotional and

mental disturbance receive a high priority. This is a position with which, hopefully, few psychologists will take issue. Although psychology possesses many techniques to effect remediation of mental and emotional disturbances, the expense of remediation in terms of professional time, money, and wasted human potential is probably much greater than adequate prevention programs.

Given that few psychologists would quarrel with an emphasis on prevention, it becomes necessary for the profession to determine which detrimental behaviors should be attacked first. Although it is beyond the expertise or desire of the present writer to rank order the problem areas on a priority basis, such an endeavor seems timely. Perhaps a panel of experts in psychopathology could be assembled under the auspices of APA to begin this awesome task. Several potential questions related to priority setting might include the following:

1. What proportion of the population evidences symptoms?
2. How handicapping is the pathology?
3. Is the course of the pathology progressive?
4. Is there a known etiology?
5. Are specific measures available which are likely to prevent its occurrence?
6. What resources are necessary to accomplish prevention?

CHILD ADVOCACY

The report recommends that a child advocacy system be created to guarantee the mental health of children. Specifically, it urges a federal-, state-, and local-level arrangement for advocacy of children's welfare. At the national level, the report suggests a presidential advisory council which

would be charged with the responsibility of studying and gathering information on the problems of children and youth in the United States and with doing long-range planning, policy making, and programming, both for services and for manpower. This advisory body would be concerned about how well federal agencies are working together, competing, or overlapping in providing services. It would advise the President and the Congress on the effectiveness of programs and would make recommendations for legislative and program changes and in the allocation of monies spent for children and families [Joint Commission, 1970, p. 8].

In the process of developing a child advocacy system, the consumers of services must be heard. When children are unable to speak effectively for themselves, their parents will have to serve as first-line advocates and determiners of policy. It is

interesting to note that government is sensitive to this issue. Paul and Neufeld (in press), for example, have recently pointed out that in 1970, Public Law 91-517 established councils at the state and federal levels for the developmentally disabled. That law requires each state council to submit statewide plans for developmentally disabled children. Further, it specifies that one-third of the council's members at both the state and federal levels consist of consumers.

UNIVERSALLY AVAILABLE PRESCHOOL PROGRAMS

Pressures continue to increase for the establishment of year-round preschool educational programs. The demand for this service comes both from those who seek to ensure equal career development opportunity for women and from those who see such a service as a means to eliminate cultural-familial mental retardation. It is the latter issue which is particularly relevant to the mental health "crisis" alluded to in the report.

Evidence has existed for some time indicating that cognitive differences between low- and middle-income children begin to appear under three years of age (Bayley, 1965; Knoblock & Pasamanick, 1953). More recently, Wachs (1967) has reported significant social class differences in sensorimotor development in infants under one year of age, using the Piagetian-based Uzgiris-Hunt Scales of Infant Development.

If Bloom's (1964) idea that an organism is most easily changed during periods of rapid transition is valid, ought not we as psychologists seriously advocate programs which begin during early infancy and aim to prevent the onset of developmental impairment?

An examination of results from research-oriented day care and preschool programs is encouragement for the universal availability of such programs. Results from both center-oriented and home-oriented preschool programs indicate that disadvantaged children who participate in such programs show superior intellectual performance relative to nonparticipating children (e.g., see recent reports by Gordon, 1972; Heber, 1971; Klaus & Gray, 1968; and Levenstein, 1970). These projects, and others which currently exist, are probably best regarded as pilot projects rather than as definitive evidence for the beneficial effects of early intervention. Nevertheless, the bulk of the evidence certainly seems to indicate that the opportunity to participate in such programs is advantageous for

the disadvantaged child, at least while he participates in the program. Thus, in principle, the recommendation by the Commission to support high-quality preschool education, particularly for our disadvantaged children, seems sound and prudent.

INCREASED SUPPORT FOR RESEARCH

It is not unlikely that in an article of this type there should be a plea for expanded support for research. Yet, the recent trends in research funding at the federal level for basic and applied research seem to make such a request both timely and necessary. It is almost inconceivable that at a time when this country continues to grapple with major problems in education, desegregation, poverty, and alienation that there appears to be a reduced commitment to the investigation of these conditions. Had we as a nation succeeded in remedying these malevolent situations, then reduced support for research in these areas would be warranted. Such is not the case, however. The "crisis" which was acknowledged in the Commission's report in 1970 has not been passed. Indeed, a good case could be made that the intensity of the crisis has increased.

To combat successfully the forces which threaten the well-being, if not the very life, of our society, research should be fully supported in at least the following three areas.

First, nationwide epidemiological studies should be undertaken to document precisely the extent to which the young of our nation are thwarted in the full realization of their developmental potential.

Second, more adequate assessment and evaluation of action-oriented social programs should be undertaken immediately. In the future, detailed evaluation strategies should be planned from the very beginning. It is naive to believe that all, or even most, pilot or demonstration projects will be successful in ameliorating the adverse effects of deplorable social conditions. However, it is only through the careful scrutiny of adequately collected data that those programs which are effective can be identified and their successful components disseminated.

Third, basic multidisciplinary research into the causative factors underlying unrealized potential should receive increased support. Realizing that a variety of levels of explanation are needed to understand fully social phenomena, encouragement and incentives should be provided for more collaborative multidisciplinary research efforts.

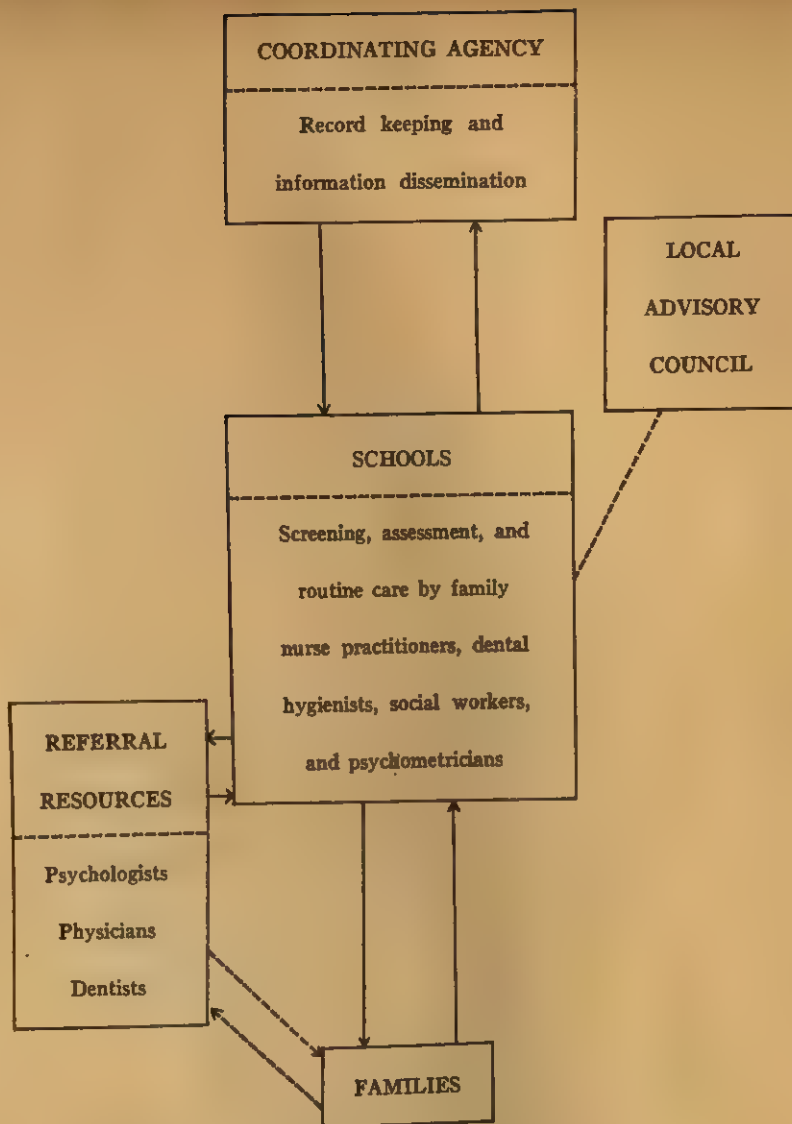

Figure 1. A delivery system for health services.

A General Model for Delivering Services to Children and Families

The main function of this system is to monitor the physical and mental health of this country's children and to provide necessary preventive and remedial services. A child would be enrolled in this system during his mother's pregnancy and would remain in it until adulthood.

The major premise on which the model to be presented rests is that a truly effective delivery system will have to be national in scope. Given that this nation's population is highly mobile geographically, it is mandatory that a system be devised which will be able to maintain contact with transient as well as permanently located families.

Because geographical mobility shows no signs of abating, the ability to serve this wandering population in the future will probably be even more difficult to maintain.

The following are major problems which should be considered by any truly comprehensive delivery system for mental-health-related services for children:

1. Prevention of developmentally disabling social conditions.
2. Screening and assessment for early signs of dysfunction.
3. Ready availability of facilities for prompt treatment of minor maladies.
4. Fast referral for extensive treatment.

5. Local follow-up on outcomes of referral.
6. Maintenance of usable and transportable records.
7. Coordination of information flow.

Figure 1 contains a schematic outline of the proposed delivery system. This model has several structural features which need comment. It will be noticed that local schools serve as the primary point of intersection for families and relevant professions. Although many school systems have historically fulfilled much the same role as will be proposed here (particularly for the poor), there does not appear to be a plan for using this site to provide services on a coordinated nationwide basis.

The school has been chosen as the first-line screening, assessment, and treatment center for several reasons. First, schools are primarily neighborhood based and therefore easily accessible to the populations that need to be served. Second, they represent a sophisticated network of physical facilities, which could be used (with minor modifications) in lieu of the creation of new facilities. Third, schools are underused on a time basis.

Each participating school would have assigned to it a team of professionals to provide routine screening, assessment, and minor treatment. Such a team might include family nurse practitioners, dental hygienists, social workers, and psychometricians. Problems which required more refined diagnoses or treatment would be referred to a second-level professional group to include, among others, psychologists, physicians, and dentists.

Attached to each school there would be a local advisory council consisting of representatives from various health professions, teachers, and parents. The role of this group would be to monitor the system and to serve as a liaison between the system and the consumers of services.

The coordinating agency should be one that can maintain and disseminate information to relevant individuals on a national scale. Records need to be quickly and accurately transferable to new locations as families move, in order to insure continuity of care and treatment. A likely candidate for this function might be the Social Security Administration.

The main advantage of adopting a service delivery system for children based on this model is that

an efficient consolidation of services would be possible. Our current fragmented delivery system, which misses many of the children who most need services, could be replaced by a comprehensive system which would guarantee high-quality care and treatment to all children. Further, much more efficient use of professional time would be possible.

The nationwide adoption of a system based on the model which has been sketched here would allow the continuous monitoring of trends in the mental and physical health of our nation's children. The information generated by periodic screening and assessment and by prompt treatment would serve as a data base for the modification of system characteristics based on the current needs of the population. Through a process such as the one which has been proposed this nation could reaffirm through meaningful action its concern about its young.

Implications of Developmental Theory for Child Mental Health

JEROME B. DUSEK *Syracuse University*¹

Following extensive study, the Joint Commission on Mental Health of Children (1970) recently published its findings and recommendations regarding a number of broad issues pertinent to the mental health of children and youth. The foundation of the report is the Commission's suggestion that rather than allow poor mental health to occur and then administer treatment, a system should be established to *prevent* the occurrence of poor mental health in children.

In order to obtain an atmosphere in which prevention of poor mental health is positively viewed and supported, the Commission argued for what is essentially a child's Bill of Rights, including,

the right to be wanted, the right to be born healthy, the right to live in a healthy environment, the right to satisfaction of basic needs, the right to continuous loving care, the right to acquire the intellectual and emotional skills necessary to achieve individual aspirations and to cope effectively in our society, and the right to receive care and treatment through facilities which are appropriate to their needs and which keep them as closely as possible within their normal social setting [pp. 2-3].

It should be pointed out that although the Commission was clear in stating that these should be the rights of all children, the basic concern was with children from poorer socioeconomic backgrounds in which these kinds of assurances are not normally given. It should also be noted that many of the Commission's recommendations are relevant to development during adolescence and adult life as well as childhood.

In order to insure these rights to all children, the Commission offered a number of recommendations regarding implementation of environmental

conditions conducive to these rights. The Commission recommended the establishment of a child advocacy system at the local, state, and national levels; community services and programs of a supportive, preventive, and remedial nature; research programs, both "basic" and "applied," with a positive national view toward research endeavors; and manpower and training programs to both insure jobs for those in need and to provide the manpower for community-based programs. The first two proposals, as detailed in the Commission's report, may be broadly conceived as a package of procedures and programs for guaranteeing delivery of preventive and remedial services to children. The latter two proposals provide the means to present the crucial information and manpower necessary to accomplish the former.

The purpose of the present article is to discuss several aspects of the Commission's report in an attempt to define areas in which professional psychologists may contribute to the realization of the goals established by the Commission. The article deals primarily with issues of a research nature and, as such, is addressed primarily to psychologists working in university or other research settings. Following a brief presentation of the developmental view of child psychology, several implications of this point of view for basic and applied research relevant to child mental health are examined.

The Developmental View

As a basis for its recommendations, the Commission took a broad definition of the concept of mental health founded on a developmental orientation. As a result, the Commission discussed child mental health within a cognitive capacity, both potential and achieved, as well as a physical health framework. As used in the Commission's report, it is difficult to define what is meant by *developmental view* or *developmental level*. Historically, these terms have been used in several different ways,

¹ The author is indebted to William J. Meyer for his constructive criticism of earlier drafts of this article. Thanks are also due Barbara McClure and David Goldstein for their helpful comments.

each having its implications for the study of child development and child mental health. One interpretation is the rather naive, simplistic notion referred to by Kessen (1962) in his description of the literary-evocative, or metaphorical, use of the term *stage*. As noted by Kessen, this usage is limited in its utility for describing and explaining behavior. A second interpretation of developmental view is a maturational one in which the primary cause for development rests in the genetic material of the organism (Kessen, 1965). This approach is perhaps best exemplified by the extensive work of Gesell (e.g., 1928) and is typically characterized by the use of chronological age as a major factor to explain development. Kessen (1962) has discussed the implications of using age as an explanatory variable. Finally, the currently prevalent view in much of the professional literature refers to a theoretical orientation based on the organismic model of man. The implications of this manner of viewing the developing organism have recently been discussed by several authors (e.g., Langer, 1969; Reese & Overton, 1970). Briefly, the organismic model holds that man is a living, organized system which is inherently and spontaneously active. As opposed to the mechanistic, or learning theory, model of man, which is not a developmental model (Kessen, 1962), qualitative changes in the structure of the organism are accepted as given. Emphasis is on the explication of the nature of the processes producing these qualitative changes. This view will be explicated in detail, since it is the writer's opinion that it has important implications for development.

Application of the organismic model of man to the description of the psychological development of the child entails several basic assumptions with respect to building theories of development. One such assumption is that development will proceed through an invariant sequence of stages, each stage defined by the cognitive structures of the organism and existing in a hierarchical relationship to preceding and future stages. These and other implications of stage theory have been discussed in detail by Flavell (1963) and Kessen (1962). A second basic tenet of cognitive theories of development is the distinction between a child's performance and competence (Flavell & Wohlwill, 1969). Performance is viewed as simply a measure of the child's behavior in a given situation at a given time and not as a measure of the full range of his capabilities with respect to that situation. An excellent

example of this notion may be found in studies of language development. The language used by a child may not reflect all of his capabilities with respect to language (Chomsky, 1964). Ginsburg (1972) has extrapolated this issue with respect to the study of the psychological development of deprived children. A third basic assumption is that of internal motivation (Hunt, 1963, 1965). As noted above, the organism is viewed as inherently active. Within cognitive developmental theories, this motivational statement is the basis of development, which involves transformations of cognitive structures due to organization of systems of internal relations through interaction between the structures of the organism and structures of the environment. The direction of development is toward greater equilibrium in organism-environment interactions (Flavell, 1963; Kohlberg, 1969).

IMPLICATIONS FOR BASIC RESEARCH RELATED TO CHILD MENTAL HEALTH

Although a large volume of research based on this theoretical orientation to development has been conducted, there are a number of basic research issues in need of further investigation in order to clarify various aspects of the general developmental model. Although conceived within a basic research framework, these same issues may be crucial to a better understanding of child mental health. For example, research investigating the cognitive development of black children is a prerequisite to implementation of the Commission's recommendation for the development of diversified elementary school curricula responsive to the needs of children. What is currently known of cognitive development in black children is based on comparative research, that is, research in which the performance of black children has been compared to the performance of white children. The emphasis in much of this research has been on what competencies black children *do not* have rather than on competencies possessed by black children. The typical end result of this comparative approach is that black children do "less well" than white children and are, therefore, inferior in development. There are at least two serious implications of this type of research.

One implication is that relatively little is learned about the general nature of cognitive development in black children. Until such knowledge is gained, it will remain difficult, if not impossible, to determine whether previously shown ethnic group differ-

ences in development are due to a "lag" in development or are due to a qualitatively different nature of development. Of course, the same types of arguments may be made with respect to other ethnic groups or in regard to social class or other individual difference comparisons of development. The crucial point is not that comparative research of this nature should not be done, for that is up to the individual investigator. Rather, the value of noncomparative research strategies may go much further toward giving a more complete understanding of development than is possible with comparative strategies. In so doing, such an approach will also provide information relevant to program and curriculum development deemed desirable by the Commission. For example, rather than research aimed at demonstrating gain in ability as a function of intervention programs, what is needed is support for research focused on identifying competencies and programs developed to match and build on these competencies. The end result, then, is that relatively basic research provides information both for general development of the field and for programs devised for improving child mental health.

A second, and increasingly more important, implication of the comparative research strategy is its effect on special interest groups in the community. These groups are becoming more active in demanding prior approval of research to be conducted in schools attended by their children and are typically fearful of research comparing their children to children in the white community. It is noteworthy, in this context, that the Commission apparently felt compelled to preface its recommendations with the statement that "a high priority must be given to the establishment and preservation of a national research climate which optimizes the productivity and opportunities of the individual researcher [Joint Commisison, 1970, p. 17]." Clearly, greater community backing for research endeavors will be needed in the future. This backing is more likely to be obtained if the research is not of a comparative nature, but rather is aimed at providing answers to questions of concern to the community.

The above should not be considered a diatribe against comparative research, but rather as a reminder that there are meaningful questions about development which do not demand the comparative approach. Moreover, the application of findings from developmental research to child mental health may be facilitated by noncomparative research.

Finally, community participation in research relevant to the advancement of theorizing about development may be enhanced if the research is not of a comparative nature. Noncomparative research will add to our ability to explain development, and thereby advance developmental theory, but will also provide information invaluable for the application of developmental theory to the everyday problem of guiding child development in the community.

A second, but related, area in need of considerable investigation is the relationship between development in one skill area (e.g., cognitive) to development in other skill areas (e.g., affective or language skills). Kohlberg (1969), for example, has argued that cognitive skills and affective skills (e.g., moral judgments) develop in parallel and independently. To the extent that this is the case, the child may be at different developmental levels on tasks representing different skills, making statements regarding general developmental level as dubiously useful as the traditional IQ concept (Guilford, 1967). What may be necessary is a model of cognitive development similar to Guilford's structure of intellect in which a profile of the child's current developmental levels (stages) is available. Future basic research in this area should clarify these matters and allow the determination of educational programs aimed at building the child's competence to new levels based on his current level of functioning.

Finally, in order to achieve a more complete understanding of development, it will be necessary to conduct large-scale life-span research. Although the Commission argued that further research was needed in the neglected age ranges of 1-3 years (toddlers) and 21-55 years, it must be argued that the most important information for a developmental view would come from studies focused on the development and change in competencies and over longer periods of the life-span at the infancy and childhood levels. In addition to the problems traditionally involved in longitudinal research, for example, sample attrition, cost, etc., at least three other problems must be solved: research design issues, interpretation of task behavior at various age levels, and the determination of tasks appropriate over a wide age range, particularly early to late childhood.

The problem of appropriate longitudinal research designs has recently been discussed by Schaie (1965, 1970) and Nesselroade (1970) and need not be elaborated here. It is sufficient to state that

research designs are available in which data from life-span longitudinal research may be evaluated without confounding age, cohort, or time of measurement effects. It should also be kept in mind that strong arguments for single-subject designs for the assessment of developmental change may also be made (e.g., Hoyer, 1972), thus eliminating some of the problems traditionally associated with longitudinal studies.

A considerably more complex and serious issue is that of the interpretation of behavior at various age or developmental levels. Within cognitive developmental theory, this issue relates to determining the rules of transition of the child's cognitive structures from a relatively lower to a relatively higher level of functioning. Kessen (1962) has discussed this problem and its theoretical implications for cognitive development. The opportunities and need for basic research in this area are obvious and multitudinous.

Perhaps the most difficult of the three problems is the development of tasks that are appropriate for children at different developmental levels of functioning and that allow the assessment of cognitive functioning, that is, the assessment of rules of functioning, at different developmental levels. Although several such tasks are available, for example, probability learning (Weir, 1964) and conservation (Flavell, 1963), this problem remains one of the most difficult yet most important for those interested in conducting developmental studies covering the infancy through adolescent years. This problem is especially important if the assessment of cognitive change from one level to another in development is to be assessed.

As research findings elucidate the concept of developmental level and as better techniques are developed for measuring the child's current level of functioning, appropriate methods must be developed in order to help the child attain the highest possible developmental level in various skill areas. Although it will undoubtedly be necessary to develop new teaching materials based on views consistent with the developmental model outlined above (for example, see Furth, 1970), it must be kept in mind that a vast amount of research involving behavioral technology based on the mechanistic model of man (Bijou & Baer, 1961, 1965; Reese & Overton, 1970) is available for altering children's behavior in various situations. Although these techniques are antithetical to the developmental model, they, nevertheless, may prove useful as

tools to alter the child's behavior in such a way that he better attends to tasks aimed at increasing his cognitive competence in some skill area or for teaching certain basic skills prerequisite to more complex levels of functioning.

IMPLICATIONS FOR APPLIED RESEARCH RELATED TO CHILD MENTAL HEALTH

The Commission made a strong plea for applied research related to child mental health. Included among their recommendations were short-range applied projects planned on the basis of productivity at a given time in the nation's history, evaluation of various forms of therapeutic intervention programs, training in research manpower, comparative studies of various forms of intervention procedures, and research projects designed to evaluate and assess the action programs proposed by the Commission. Although these are basically applied research projects, a number of them are directly researchable from a developmental view and have direct relevance to this view.

One example might be to investigate the characteristics of children that relate to success in various day care programs as defined by the objectives of the program, that is, interact child characteristics with program characteristics. It should then be possible to develop techniques for determining the best program, for example, open environment versus more structured programs, for children with certain specified characteristics. To the extent that children's attitudes, characteristics, and cognitive competencies relate to the success of a program, this research, which would most likely have to be longitudinal, is crucial to program development. This approach would allow meaningful developmental research into children's cognitive competencies which is applied in nature, but not comparative, and which has obvious ties to basic developmental research as described above.

As a knowledge base concerning child and adult cognitive competency is built from basic research programs, this information may be incorporated into applied research programs aimed at training adults who work in child care settings. Various training methods for adults working in child care programs of different philosophical orientations may be developed. It should then be possible to interact adult characteristics with program characteristics in order to determine the best way to teach child care information to adults with various cogni-

tive or social competencies. Since the development of cognitive competency in children is related to the cognitive competency of the adults teaching children, it is obvious that this aspect of an applied research program is of critical value to the success of various day care and nursery school programs. Changes in children's behavior, as a function of the training of adults who work in various child care programs, should also be evaluated.

Obviously, a large number of applied projects of this sort are possible, each contributing to a more complete understanding of issues in child mental health as well as the remedial/preventive atmosphere suggested by the Commission. At the same time, however, these projects provide a testing ground for developmental theory as briefly described above and, as such, feed directly into basic research programs. As a result, the dichotomy between basic and applied research begins to fade as each feeds into the other. There remain two critical issues. First, in order to do this, psychologists, and others, must become interested in the application of developmental theory to everyday child development situations. In other words, the difficult job of translating theory into practice must be tackled, either by the researcher-scholar or by people trained in a way that allows them to do this. Fortunately, some of this kind of work is being done. Second, and perhaps more crucial, is the fact that large-scale research projects of this sort, in which both "basic" and "applied" research are coordinated, require large sums of money for implementation. Current funding levels are not encouraging of the time and effort required to design and plan this type of project. If, as the Commission proposed, we are to make a concerted effort to improve the lives of our children, funds for large-scale programs of this nature will have to be made available.

Summary

Included in the Commission's report are a number of principles, suggestions, and recommendations which are certainly deserving of careful thought and consideration and which will no doubt stir considerable controversy, for example, child advocacy systems, the definition of a mentally healthy child, and a federally paid allowance to children of poverty backgrounds. The undertaking of the Commission was no doubt arduous and the recommendations were bold.

An attempt has been made here to spell out some of the ways in which a developmental view may contribute to a unique understanding of issues related to child mental health. This unique view is the result of theorizing and application based on a conception of the child as a developing organism undergoing qualitative changes with the emphasis on development and change. Although others favoring this view may have written more eloquently and expertly, and those favoring other views may disagree with certain of the arguments presented above, it is clear that this approach has something significant to offer vis-à-vis child mental health.

Scientific Awards Announcement

The Committee on Scientific Awards is accepting nominations for its award program. The Committee selects up to three persons as recipients of the Distinguished Scientific Contribution Award who, in its opinion, have made the most distinguished theoretical or empirical contributions to scientific psychology in recent years.

A new award, the Distinguished Contribution for Applications in Psychology, has been authorized by the Board of Directors and will be given for the second time this year. This award will be presented to an individual who, in the Committee's opinion, has engaged in a program of research which is systematic and applied in character.

The awards are subject to the following limitations: (a) members of the Committee, former recipients of the awards, the President and the President-elect of the APA shall be ineligible. (b) The Committee shall seek diversity in selecting recipients, avoiding as far as possible the selection of more than one person representing a specialized topic, a specific material, a given method, or a particular application.

Names and appropriate information which will guide the Committee on Scientific Awards in conducting an intensive career review and evaluation should be forwarded to Office of Scientific Affairs, American Psychological Association, 1200 Seventeenth Street, N.W., Washington, D.C. 20036. *Deadline for nominations is March 1, 1974.*

A New Tabulation of Statistical Procedures Used in APA Journals

EUGENE S. EDGINGTON *University of Calgary*¹

In Edgington (1964), a tabulation was presented of statistical procedures used in APA journals from 1948 to 1962. The tabulation was intended to serve as a guide in the organization of statistics books and courses for psychology students inasmuch as frequently used statistical procedures are not only those that the student needs to understand in order to interpret psychological publications, but are also those that the student is likely to find useful for data analysis. This article brings the tabulation up to date for the same journals or their successors.

The journals examined for the current tabulation were the APA journals primarily concerned with original empirical research: *Journal of Abnormal*

Psychology, *Journal of Applied Psychology*, *Journal of Comparative and Physiological Psychology*, *Journal of Consulting and Clinical Psychology*, *Journal of Educational Psychology*, *Journal of Experimental Psychology*, and *Journal of Personality and Social Psychology*. All articles in these journals for the even-numbered years from 1964 to 1972 (except the 1966 issues of the *Journal of Educational Psychology*, which were not available) were examined to determine what kinds of inferential statistics, if any, were used. The results are presented in Table 1 along with the previously published results for 1948–1962. Observe that the percentages in Table 1 are based on all articles involving statistical inference, not on all articles in the journals. (Ninety-one percent of the articles involved statistical inference.)

Table 1 shows that by 1972, 71% of the articles using statistical inference used analysis of variance.

¹ Requests for reprints should be sent to Eugene S. Edgington, Department of Psychology, University of Calgary, Calgary 44, Alberta, Canada.

TABLE 1

Number of Articles Using Types of Statistical Procedures Expressed as Percentages of Number of Articles Using Inferential Statistics

Year	No. statistical inference articles	Percentages					
		Analysis of variance	<i>t</i> test ^a	Correlation ^b	Chi-square ^c	Factor analysis	New non-parametric ^d
1948	204	11	51	42	10	1	3
1950	310	16	47	38	19	3	3
1952	458	24	44	32	16	4	7
1954	529	34	34	33	14	3	13
1956	587	38	29	32	16	3	16
1958	689	41	26	29	16	4	17
1960	593	42	23	28	12	5	20
1962	775	55	19	24	10	5	20
1964	674	58	18	20	17	4	19
1966	925	62	18	20	16	2	19
1968	1,128	69	13	21	16	2	17
1970	1,170	70	13	25	12	3	14
1972	1,195	71	12	25	15	4	12

Excludes tests in connection with analysis of variance.

^a Tests involving the use of either *t* tables or normal-curve tables. Excludes correlation techniques and Spearman's rank-difference method. Excludes correlation coefficients computed for factor analysis.

^b Parametric correlation techniques and Spearman's rank-difference method. Excludes correlation coefficients computed for factor analysis.

^c Traditional chi-square procedures.

^d All nonparametric techniques not in correlation and chi-square categories.

For the 1972 journals, a separate count was made of simple one-way analysis of variance and more complex analysis of variance techniques. It was found that although simple one-way analysis of variance was frequently used, 88% of the analysis of variance articles employed repeated-measures designs or factorial designs instead of, or in addition to, simple one-way analysis of variance. (Factorial designs were employed more frequently than one-way repeated-measures designs.) Repeated-measures and factorial analysis of variance techniques are not commonly included in introductory statistics books, and so it is likely that they also are not generally included in the introductory course. The extent to which these procedures are used, however, suggests that they should be taught. Time for teaching these procedures could be acquired by not teaching independent and correlated *t*-test techniques, which are redundant when both simple and repeated-measures analysis of variance are taught. Inasmuch as there is frequent reference to *t* tests in the journals, however, the function served by them should be explained in terms of the corresponding analysis of variance tests.

Correlation and traditional chi-square procedures are used frequently and certainly serve distinctive functions, which should assure them of a place in introductory statistics books and courses. These procedures are, of course, usually taught, and so the recommendation made here is to retain them. Similarly, factor analysis is *not* a standard technique for an introductory statistics course, and it

should *not* be a part of the course because it is used so infrequently. The "new nonparametric techniques," which exclude traditional chi-square procedures and Spearman's rank correlation, are used in all of the journals to some extent and in some journals rather frequently. The overall extent of use merits a general discussion of nonparametric statistics in the introductory course, but not a detailed discussion of a number of techniques. Of the 798 articles for the years 1964-1972 that used new nonparametric techniques, half made use of the Mann-Whitney *U* test, so there may be reason to discuss this test, but no other new nonparametric test approached such widespread use.

Tables like Table 1 were constructed for each of the seven journals to permit comparisons across journals. Variation among the journals in the use of statistical procedures was found, but there was also considerable agreement. For example, every one of the journals showed an upward trend in the use of analysis of variance, and in every journal the use of complex analysis of variance techniques in 1972 far outnumbered the use of simple one-way analysis of variance.²

² The author will send separate tables for the seven journals to readers requesting them (see address in Footnote 1).

Contributions to Education in Psychology Awards

The American Psychological Foundation invites nominations for the 1974 Contributions to Education in Psychology award. The annual award is in the amount of \$1,000 to be given to the recipient for his achievements. It is hoped that the awardee's institution will contribute a matching sum, thus providing the recipient with a modest "grant" to be used by him as he wishes to "improve the teaching of psychology." Thus, the objective of the award program is to enhance the local instructional program, not just to recognize "master teachers." Because the awards are to be presented at the APA Annual Convention in September 1974, *nominations must be completed and sent to the Committee by March 31, 1974*. A nomination form with a statement of the guidelines and suggestions for documentation can be obtained by writing to Irwin J. Knopf, Chairman, APF Teaching Awards Committee, Department of Psychology, Emory University, Atlanta, Georgia 30322.

Distinguished Scientific Contribution Awards for 1973

The Awards for Distinguished Scientific Contribution are presented by the Association at the annual convention. The awardees for this year, along with those for the preceding years since the establishment of the custom, are:

1956	1957	1958	1959
WOLFGANG KÖHLER CARL R. ROGERS KENNETH W. SPENCE	CARL I. HOVLAND CURT P. RICHTER EDWARD C. TOLMAN	FRANK A. BEACH PAUL E. MEEHL B. F. SKINNER	LEON FESTINGER DONALD B. LINDSELY NEAL E. MILLER
1960	1961	1962	1963
HARRY F. HARLOW CHARLES E. OSGOOD S. SMITH STEVENS	JAMES J. GIBSON DONALD O. HEBB HENRY A. MURRAY	JEROME S. BRUNER WILLIAM K. ESTES HARRY NELSON	ROGER G. BARKER GEORGE A. MILLER CARL PFAFFMANN
1964	1965	1966	1967
GORDON W. ALLPORT WENDELL R. GARNER J. P. GUILFORD	FLOYD ALLPORT FRITZ HEIDER PAUL THOMAS YOUNG	NANCY BAYLEY CLARENCE H. GRAHAM RICHARD L. SOLOMON	SOLOMON E. ASCH ERNEST R. HILGARD JAMES OLDS
1968	1969	1970	1971
JAMES E. BIRREN ELEANOR J. GIBSON MUZAHER SHERIF	JEAN PIAGET STANLEY SCHACHTER HERBERT A. SIMON	DONALD T. CAMPBELL DAVID KEECH R. DUNCAN LUCE	ROGER WILLIAM BROWN HAROLD H. KELLEY ROGER WOLLCOTT SPERRY
	1972	1973	
	EDWIN E. GHISELLI DOROTHEA JAMESON AND LEO HURVICH PATRICK SUPPES	LEE J. CRONBACH CONRAD KRAFT BRENDA MILNER BENTON J. UNDERWOOD	

Cronbach, Kraft, Milner, and Underwood were each presented with an engrossed citation of his/her formal contributions to the development of scientific psychology and a check for one thousand dollars. These psychologists have agreed, in accordance with established custom, to present addresses on some phase of their scientific work at the 1974 Convention. The presentation of awards was made by R. Duncan Luce, Chair of the Committee on Scientific Awards. Other members of the Committee are Herschel Leibowitz, Brendan Maher, James Olds, Harold H. Kelley, and James J. Jenkins.

Lee J. Cronbach

CITATION

"For his singularly outstanding contributions to psychometric theory and application. His work on reliability theory, interpretations of test validity, and basic concepts in decision making based on measures of individual differences has influenced the foundations of our science. His analysis of the relationships among various disciplines of psychology has pointed to new problems for investigation. His exceptionally clear and well-organized textbooks on

psychological testing and educational psychology are read throughout the world. His analysis of educational evaluation has strengthened the contribution of psychological research to education. As an individual, he is widely respected for his sustained devotion to the problems he addresses and for his ability to focus with insight on the relevant issues involved."

BIOGRAPHY

Lee J. Cronbach was born April 22, 1916, in Fresno, California. After graduating from Fresno High

Lee J. Cronbach

School he completed the AB degree at Fresno State College in 1934. He obtained a secondary teaching credential at the University of California, Berkeley, in 1935, and taught mathematics and chemistry from 1936 to 1938 at Fresno High School. He also received the master's degree from the University in 1937. His doctoral program under G. T. Buswell and R. W. Tyler in the Department of Education of the University of Chicago (1938-1940) provided training for educational research. He served for one year as research assistant in the Evaluation Staff of the Eight-Year Study, and received his doctorate in 1940.

Most of his education in general psychology came when, as half of the two-man psychology faculty of the State College of Washington, he found himself teaching many courses he had never taken. In this position (1940-1946) he also directed a reading clinic and assisted in student personnel programs. In 1944 and 1945 he was on leave to work under Adelbert Ford, in a personnel research and development office established by the National Defense Research Committee at the U.S. Navy Radio and Sound Laboratory. There he validated personnel

tests, and designed and evaluated an instructional program for training sonar operators to discriminate underwater sounds.

Cronbach returned to the University of Chicago as assistant professor of education in 1946, and in 1948 moved to the University of Illinois as associate professor of education, and later professor of education and psychology. The Illinois appointment was in the Bureau of Educational Research, and provided freedom and encouragement to work on fundamental questions relevant to education. After 16 years at the University of Illinois he moved to Stanford University, where he is Vida Jacks Professor of Education with responsibilities in training for educational research.

Cronbach's research, being primarily methodological, has often taken its direction from the difficulties encountered in the research of colleagues and in projects to which he has been a consultant. At the University of Chicago, he was exposed to the personological studies flourishing around Robert Havighurst, Carl Rogers, and W. E. Henry. Their dynamic assessments of the person appeared to be ill-served by traditional methods of validating test interpretations. Cronbach produced papers suggesting new approaches to test validation and a textbook that emphasized general critical principles of test development and use. The work was carried further when Cronbach was asked to chair the Committee on Test Standards of the American Psychological Association. To develop a code for maintaining the quality of tests of ability and personality, it was necessary to reconsider the entire logic of validation. Paul Meehl, out of his study of the philosophy of science, developed a committee paper which contained the basic idea of construct validation. This idea was carried further by the committee, and ultimately was elaborated into the well-known Cronbach-Meehl (1955) exposition. (The toss of a coin determined the order of authorship.)

Consultation with the Kelly-Fiske project on assessment of clinical psychologists led Cronbach into a program of studies (1951-1958) on empathy and the perception of others, partly in collaboration with Fred E. Fiedler and N. L. Gage. In describing empathy, similarity between persons, and projection, and also in the application of tests in the clinic, the analysis of score profiles loomed large. To clarify the logical issues in profile analysis, Cronbach enlisted Goldine Gleser, then associated with clinical research at Washington University, as

co-worker, thus launching a 20-year collaboration.

While consulting with a Navy laboratory regarding sonar training, Cronbach was introduced to Shannon's information theory; he and Gleser set out to trace its possible use as a basic model for psychometrics. Information theory proved unsuitable, but led them ultimately to treat test interpretations as rules for decision making, applying the more elaborate model of statistical decision theory. Cronbach's next collaboration with Gleser turned into a nearly unending project. At the outset, it was their intent to put the ideas of measurement theory, new and traditional, into a straightforward but unified exposition. Almost at the outset, however, contradictions and puzzles turned up which were resolved only by the production, some 15 years later, of a monograph introducing a new "theory of generalizability." This theory embraces much of classical theory but offers more flexible and constructive analyses, and brings to light problems previously unrecognized. The 1972 work ended where the 1952 collaboration began, with suggestions for modifying the way in which profiles of test scores are used.

New problems also emerged from the earlier work on decision theory. As Cronbach pointed out in his 1957 APA Presidential Address, the decision analysis showed that neither the traditional methods of the experimenter nor those of differential psychology are adequate to investigate responses to treatments or to validate tests for purposes other than selection. The interactions to which he directed attention have increasingly become a concern in research on mental processes, on personality, and in several applied fields. Since 1965 Cronbach has been engaged with R. E. Snow and many students in substantive and methodological work on interactions, with particular reference to adapting instruction to the individual. A treatise on this "new discipline" of psychology is near completion. Cronbach's other recent writings reflect a concern for the social policy underlying the use of tests, which has led him into studies of the history of testing and its social influences. Cronbach is also engaged with R. R. Sears in a study of the career development and social contributions of the Terman "gifted" sample.

Cronbach's approach to curriculum and instruction, expressed particularly in his textbook on educational psychology, was primarily the outgrowth of his years at the University of Chicago. Teaching the undergraduate course there in 1946-

1948, he followed Tyler in urging that classroom practice be aligned with psychological findings, particularly those on the generalization and transfer of learning. Cronbach followed Havighurst and Prescott in interpreting the pupil's response to schooling as a reflection of and a vehicle for his continuing development as a person. Except for wartime work on training materials and some unpublished local studies of instruction at the University of Illinois and Stanford University, Cronbach has done little direct educational evaluation; his ideas have developed mostly through his role as a consultant. He followed closely the applied work of the Unit on Evaluation at Illinois under J. T. Hastings, and later was consultant on measurement for national projects seeking to reform science and mathematics curricula and for the National Assessment of Educational Progress.

In 1955-1956 Cronbach served as scientific liaison officer in the Office of Naval Research, London, and in 1967-1968 he was Fulbright lecturer in the Faculty of Education of the University of Tokyo. From 1961 to 1966 he chaired the Committee on Learning and the Educational Process of the Social Science Research Council, which sought to make psychological research on learning more fruitful for education. For this committee he directed postdoctoral training institutes at Stanford in 1965 and 1966 which have been the model for subsequent international institutes in Sweden, France, Germany, and Southeast Asia.

Cronbach has served as President of APA and its Division on Evaluation and Measurement, the Psychometric Society, and the American Educational Research Association. In 1960-1961 he was a member of the Institute for Advanced Study and in 1963-1964 a Fellow of the Center for Advanced Study in the Behavioral Sciences; in 1971-1972 he was a Guggenheim Fellow. He is a member of the National Academy of Education, the American Philosophical Society, and the American Academy of Arts and Sciences. He received an honorary Doctor of Humanities degree from Yeshiva University in 1967, and the award for Distinguished Service to Educational Measurement from the Educational Testing Service in 1971.

Conrad Kraft

CITATION

"For diligence, skill, and effectiveness in applying psychological principles and knowledge to improve the efficiency and safety of man's interaction with his environment and in complex man-machine systems. His experiments reflect both a sensitivity to problems stemming from the technological nature of our society and an appreciation for the potential value of the data and methods of experimental psychology. His ability simultaneously to encompass both points of view has produced a series of unique and important contributions. In particular, his development of radar room lighting systems and his identification of a visual illusion during night visual landing approaches as a major contributing factor to a series of fatal jet aircraft accidents represent outstanding examples of his and psychology's contribution to our society."

BIOGRAPHY

Conrad L. Kraft was born in Birmingham, Michigan, on April 25, 1916, but he grew up in the western town of Rawlins, Wyoming. His undergraduate work was done at the University of Wyoming, located in the more famous city of Laramie. He began his undergraduate work in engineering, but the personality and teaching skill of Robert Hall Bruce drew him into the field of general-experimental psychology. By the time he graduated in 1939, his interest in behavioral mea-

surement was well-established, but jobs were scarce. He was first employed to make a photographic survey of the Big Horn Cattle and Sheep Company, which added to his relatively new skills in photography. This skill has since been a basic tool in much of his research.

A few months after graduation, his first opportunity to use his interest in psychophysics came with the opportunity to work with E. H. Scofield in the application of these techniques in measuring odor and taste. Scofield had just organized the Quality Research and Control Laboratory of Joseph E. Seagram and Sons at Louisville, Kentucky. The initial work of this laboratory was basic research in methodology designed to obtain the necessary reliability and validity to improve and control the quality of alcoholic beverages. The location of this laboratory in a distillery gave Kraft's father, an Episcopalian minister, the opportunity to quip, "My son is chief taster for Seagram's." Working in the laboratory were other young men who found the methodological problems most stimulating. Dean B. Foster took his interest in olfaction to Cornell University and developed the room-sized olfactometer under Karl Dallenbach. David R. Peryam extended the tasting methods to food with the Army Quartermaster Corps at Chicago in later years. Kraft, while with Seagram's, was asked to organize and develop branch laboratories in Indiana, Maryland, and Ontario in Canada. This assignment gave him experience in introducing psychological measurement into industrial organizations and in managing these laboratories.

In January of 1944 Kraft joined the Navy and its program of personnel classification and selection. This led to a short course in visual skill measurement with the Ortho-Rater from J. Tiffen and S. E. Wirt at Purdue University. Most of Kraft's wartime duty was on "the islands," Treasure and Goat, in San Francisco Bay. Building new crews for new construction destroyers and personnel transports was the major work of the classification and selection people on Treasure Island. Kraft, however, enjoyed most the chance to do some research with the Ortho-Rater, obtaining improved instructional aids, test-retest reliability, validation studies with the performance information on Combat Information Center personnel and shipboard lookouts recently returned from the Okinawa "picket line."

As 1946 brought the end of the war, Kraft returned to the University of Wyoming for his

Conrad Kraft

master's and more skills in psychology and statistics. This work under R. H. Bruce expanded his interest in vision, and in the fall of 1947 a Lumley Memorial Fellowship took him to Ohio State University to continue in this field with Sam Renshaw.

The work under Renshaw at Ohio State was to cover a number of years in a very active laboratory. The 1947-1952 period found a large number of graduate students returning from military service with a heightened interest in experimental psychology. Adams, Alluisi, Briggs, Chenoweth, G. Rowland, DeGroot, Hartman, Kelley, Pfeiffer, and F. A. Young made for a lively series of debates on any subject, theory, school, or method. Renshaw was active in bringing many of the outstanding people in the field of vision to Ohio State once a year with the vision conferences. These conferences and the workshops in behavioral optics for optometrists gave the graduate students a broad exposure to clinical and theoretical aspects of vision.

Paul Fitts had come to Ohio State in 1949, and his Laboratory of Aviation Psychology was soon to begin nine years of research in human engineering aspects of radar air traffic control. Kraft's combination of interest in engineering, aviation, vision, and methodology found a working environment much to his liking in this laboratory. Fitts' direction was stimulating, and members of the laboratory such as Schipper, Noble, McGuire, Leonard, and the Air Force monitor, Queal brought fresh ideas and a variety of backgrounds to attack the problems of a large system.

Kraft served with Jim McGuire as the technical liaison between the Laboratory of Aviation Psychology at Ohio State and Wright Patterson Air Force Base, Dayton, Ohio. This brought Kraft into contact with operational personnel and the Engineering Psychology Division of the Aero Medical Laboratory. The operational organizations provided many problems, and Kraft's interest in applying behavioral knowledge and techniques was aroused. Christensen, Warrick, and Grether at the Aerospace Medical Research Laboratory provided very sound guidance as to the workability and applicability of Kraft's endeavors to improve lighting, communications, data collection, methods of encoding information, and simulation. The juxtaposition of Fry and Enoch's laboratory to that of Paul Fitts exposed Kraft to physiological optics and the problems of the photointerpreter.

These individuals and their laboratories had marked influence on Kraft, and it is not surprising that after completing his PhD under the joint sponsorship of Renshaw and Fitts that a move to Boeing in 1959 found Kraft continuing his work in engineering psychology and vision. Boeing has provided the opportunity for Kraft to do research in these two areas, and to apply his work and that of others to the problems of man in space, the airborne observer, the photointerpreter, the industrial worker, the automobile driver, everyday safety, and the object of his special interest, the pilot. Most recently his work in vision has been in the fields of accommodation, color perception, and stereoscopic skill.

Brenda Milner

CITATION

"For outstanding psychological study of the human brain. She and her students have elucidated the role of the prefrontal lobes, previously resistant to analysis; have provided definitive data on the relation of speech localization to handedness; and have demonstrated the importance of the right temporal lobe in pattern perception (visual, auditory, tactile). Of great significance is Milner's study of the function of the hippocampus in the consolidation of memory and the devastating effect of the bilateral loss of the hippocampus on the medial aspect of the temporal lobe. The result is an inability to form new memories and an astonishing helplessness even though earlier established memories are not impaired: a dramatic demonstration

Brenda Milner

of the importance of that ability we take so lightly for granted, the ability to remember what happened 10 minutes (or more) ago."

BIOGRAPHY

Brenda Milner (formerly Langford) was born on July 15, 1918, in Manchester, England, where she attended Withington Girls' School. From there she went to Newnham College, Cambridge, to read mathematics, but after completing Part I of the Mathematical Tripos in 1937 she changed fields, graduating in 1939 with a BA degree in experimental psychology (then classed with the moral sciences). Her supervisor at Cambridge was Oliver Zangwill and to him she owes her first interest in human brain function.

After graduating, Milner was awarded a Sarah Smithson Research Studentship by Newnham College, so that she was able to stay on in Cambridge for two more years. The award coincided, however, with the outbreak of World War II, when the work of the Cambridge Psychological Laboratory (under Bartlett's leadership) was diverted almost overnight to applied research. For Milner this meant devising perceptual tasks that could be used in the selection of aircrew. Later in the war, from 1941 to 1944, she worked in Malvern as an Experimental Officer for the Ministry of Supply, investigating different methods of display and control to be used by radar operators. In 1944 she married Peter Milner and left England for Canada, supposedly for one year.

Since childhood, Milner had had a great love for the French language and had even hoped that she might one day live and work in France. When she found herself in Montreal, her knowledge of French was an immediate asset, enabling her to obtain a position at the Université de Montréal, in the newly formed Institut de Psychologie, where she set up a laboratory and taught comparative and experimental psychology from 1944 to 1952. A turning point came with the arrival of D. O. Hebb at McGill in 1947. His book *The Organization of Behavior* was still in manuscript form, and each chapter was being vigorously debated in the weekly seminar, which Milner attended. She decided to register in the PhD program, while still maintaining her teaching job at the Université de Montréal. In 1950, Hebb gave her the opportunity to study Penfield's patients at the Montreal Neurological Institute and she has remained there ever since. She obtained the PhD

degree from McGill University in 1952 and the ScD from the University of Cambridge in 1972. At present she holds the position of professor of psychology in the Department of Neurology and Neurosurgery at McGill, and since 1964 her work has been supported by the Medical Research Council of Canada through the award of a research associateship.

Milner's early work on the temporal lobes was influenced by the results of ablation work with lower primates, and particularly by Mishkin and Pribram's discovery of the role of the inferotemporal neocortex in visual discrimination learning. The visual deficits seen in patients after right temporal lobectomy indicated a convergence between the findings for monkey and man. A new departure came with the observation of global memory loss in two patients with bilateral damage to the hippocampal region, a finding which led Milner to focus much of her subsequent research on the analysis of memory disorders. In recent years she has extended her research to the frontal and parietal lobes, and has also been studying the effects of early unilateral brain lesions on the pattern of cerebral organization at maturity. Much of this work has been carried out with Laughlin Taylor, Milner's close associate for over 15 years.

Milner's work owes much to the encouragement and participation of her colleagues in neurosurgery, especially Theodore Rasmussen, as well as to the contributions of such graduate students as Doreen Kimura, Lilli Prisko, Suzanne Corkin, and Philip Corsi. She also values her collaboration with H.-L. Teuber, R. W. Sperry, and A. M. Liberman.

Milner is a fellow of APA and currently holds the office of President of the Division of Physiological and Comparative Psychology. She is also a member of several other professional societies. In 1971-1972 she returned to Cambridge University for a sabbatical year, during which time she held a 'clothworkers' Fellowship at Girton College. In 1971 she received the Kathleen Stott Prize for Medical Research from Newnham College.

Benton J. Underwood

CITATION

"For his massive contributions to the experimental and theoretical analysis of verbal learning and memory. A master of experimental design, he has been a recognized leader in the development of a modern and sophisticated methodology in his field of research. For more than a quarter of a century his wide-ranging investigations have focused on

the fundamental processes of acquisition and retention. The substantive areas in which his work has yielded new theoretical insights and basic empirical findings are too numerous to list. Among the highlights are his systematic explorations of the effects of distribution of practice, the principles of transfer, the mechanisms of interference in retention, and the role of discriminative processes in recognition. While firmly rooted in the traditions of his discipline, he has throughout his career been an innovator and a pacesetter in a rapidly growing and changing domain of research."

BIOGRAPHY

Benton J. Underwood was born February 28, 1915, in Center Point, Iowa. He received his primary and secondary schooling in Albion, Iowa, and his undergraduate degree at Cornell College, Mount Vernon, Iowa, in 1936. His goal in attending college was to qualify as a high school athletic coach. He served in this capacity for three years (1936-1939), during which period he learned that dealing with the problems of the classroom was far more rewarding than dealing with those that arose in the locker room.

He began his graduate work in psychology at the University of Oregon in the summer of 1939, but an offer of financial aid from the University of Missouri for that fall led him to Columbia. The stimulation produced by the small department at Missouri, under the chairmanship of Arthur W. Melton, led to an intellectual awakening and to a permanent imprinting of an interest in the study of human learning and memory. After the master's, he was appointed a research assistant to John A. McGeoch at the University of Iowa. The PhD was granted in December 1942. The ferment at Iowa during these years was at a peak. Spence and Bergmann were hammering out positions in a philosophy of science appropriate to psychology; the theoretical controversy between Hull and Tolman was the impetus for the activity in the animal laboratory; and the newly postulated idea of *unlearning* of associations (Melton and Irwin) guided much of the research in verbal learning. Over it all, McGeoch as chairman presided with a balancing influence which supported sound research on any topic, theoretically pointed or not.

Underwood was commissioned in the Naval Reserve in January 1943 and was assigned to the Naval Aviation Psychology Branch, headed by John J. Jenkins. Immediately after his discharge

Benton J. Underwood

in January 1946, he joined the faculty at Northwestern University, this appointment being recommended by William A. Hunt who, along with Donald B. Lindsley, also became a member of the faculty at Northwestern at that time. He found the faculty of the department and the general atmosphere of the University to his permanent liking. Both his long-term colleagues (Hunt, Duncan, Campbell) and the many who came and went provided the department with the critical research orientation needed for a first-rate department. Through the Office of Naval Research, continuity in experimentation has been possible, and there always seemed to have been two or three bright and energetic graduate students who were willing to cast their lots with a memory drum. During the 23 years of support by ONR, much of the day-to-day responsibility for Underwood's research rested on his research assistants, who were Ross L. Morgan, E. James Archer, Jack Richardson, R. W. Schulz, Geoffrey Keppel, Bruch Ekstrand, Joel Freund, and Joel Zimmerman.

Underwood has been President of Divisions 1 and 3 of the American Psychological Association, and of the Midwestern Psychological Association. In 1964 he was awarded the Warren Medal by the Society of Experimental Psychologists, and in 1970 he was elected to the National Academy of Sciences. He has served on a number of government and quasi-government boards and panels, as a consulting editor for several journals, and he is cur-

rently an Editor of the *American Journal of Psychology*. Cornell College awarded him an honorary ScD in 1966. Such events continue to amaze the former high school athletic coach.

SCIENTIFIC PUBLICATIONS

1942

Three comparisons of retroactive and proactive inhibition. *Iowa Academy of Science*, 49, 425-429.

1943

With J. A. McGECKE. Tests of the two-factor theory of retroactive inhibition. *Journal of Experimental Psychology*, 32, 1-16.

With L. E. THUNE. Retroactive inhibition as a function of degree of interpolated learning. *Journal of Experimental Psychology*, 32, 185-200.

1944

Associative inhibition in the learning of successive paired-associate lists. *Journal of Experimental Psychology*, 34, 127-135.

1945

The effect of successive interpolations on retroactive and proactive inhibition. *Psychological Monographs*, 59(3, Whole No. 273).

1948

'Spontaneous recovery' of verbal associations. *Journal of Experimental Psychology*, 38, 429-439.

Retroactive and proactive inhibition after five and forty-eight hours. *Journal of Experimental Psychology*, 38, 29-38.

With H. H. KENDLER. The role of reward in conditioning theory. *Psychological Review*, 55, 209-215.

1949

Proactive inhibition as a function of time and degree of prior learning. *Journal of Experimental Psychology*, 39, 24-34.

Experimental psychology. New York: Appleton-Century-Crofts.

Distinguished Professional Contribution Award for 1973

The second Award for Distinguished Professional Contribution was presented to David Wechsler at the Annual Convention of the American Psychological Association in Montreal on August 28, 1973. Brent N. Baxter, Chair of the Committee on Professional Awards, made the presentation. Other members of the Committee are Theodore Blau, Edward Loveland, Alfred Marrow, and Edward S. Bordin.

David Wechsler

CITATION

"His contributions to the theory of cognitive growth and his concurrent development in 1939 of the first clinical test of adult intelligence and the forms for children and preschoolers which followed it have changed the course of professional psychology, broadening its areas of application and its impact upon other professions and the public at large. These contributions used by psychologists working in hospitals, clinics, schools, colleges, and indus-

trial settings have played a critical role in the lives and careers of millions of individuals throughout the world. As one of the first presidents of the Division of Clinical Psychology and also one of the charter members of the American Board of Professional Psychology, he helped give impetus to the postwar accelerated growth of professional psychology. Kindly, thoughtful, patient, and wise, David Wechsler as scholar and clinician has ennobled professional psychology."

BIOGRAPHY

David Wechsler was born in 1896. He received his AB and MA at about the time that World War I was claiming center stage in the United States. The young scholar, as Private Wechsler, found himself involved in the large-scale intelligence testing program conducted by the Army. Thus began a fruitful interest in the measurement of intelligence, which has led to major contributions to theory and practice. After the war ended, Wechsler studied in London with Spearman and Pearson and in Paris with Henri Pieron and Louis Lapique. It was in Paris that he became interested in the psychogalvanic reflex. Later, he studied this reflex in depth in his doctoral dissertation "The Measurement of Emotional Reactions." He was awarded the PhD by Columbia University in 1925.

By 1932, Wechsler had become chief psychologist at Bellevue Psychiatric Hospital. He had already published papers in a variety of areas: studies in chronaxia, tests for taxicab drivers, the influence of education on intelligence, galvanic responses in preschool children, and others. An important article entitled "The Range of Human Capacities" was subsequently expanded and published as a book in 1935. This volume revealed that "the differences which separate the mass of mankind from one an-

David Wechsler

other, with respect to any one or all their abilities, are small" It also noted the decline of ability with age, a matter of special significance in Wechsler's later work with intelligence scales.

Starting in 1934 and continuing to the present day, he has devoted some of his enormous energy and talent to the development of the intelligence scales which are internationally known: the Wechsler-Bellevue I (1939), the Wechsler-Bellevue II or Army Wechsler (1942), the Wechsler Intelligence Scale for Children (1949), the Wechsler Adult Intelligence Scale (1955), the Wechsler Preschool and Primary Scale of Intelligence (1967), and the Revision of the Wechsler Intelligence Scale for Children (1974).

When Wechsler undertook to develop the first of his adult scales, the Wechsler-Bellevue I, he was responding to a need for an instrument that would measure adult intelligence in adult terms. He insisted that "adult intelligence cannot be evaluated in the same terms as those generally employed in defining juvenile intelligence," and that the concept of mental age for adults was misleading. He wrote:

To calculate an I.Q. for a man of 60 by dividing his M.A. score by 15, is as incorrect as to obtain an I.Q. for a boy of 12 by dividing his M.A. score by 15 for a valid evaluation of an individual's brightness, one must compare his mental ability to that of the average individual of his own age.

He produced his IQ tables by taking the age of the subjects into consideration, and thus the deviation IQ was offered for the first time in a major individual test of intelligence for adults.

During this period in the 1930s, Wechsler was crystalizing his thoughts on the measurement of intelligence. Especially noteworthy was the apparently simple but very insightful definition of intelligence that emerged in 1939: "Intelligence is the aggregate or global capacity of the individual to act purposefully, to think rationally and to deal effectively with his environment." This has been the guiding principle in Wechsler's conception of intelligence. The definition conceives of intelligence as a global entity, multidetermined and multifaceted, rather than as an independent trait. Wechsler wished to avoid designating any single ability as crucial. In particular, he wished to avoid equating general intelligence with intellectual ability. He has consistently adhered to this view. In the Manual (1974) for his Revision of the Wechsler Intelligence Scale for Children, he wrote:

To the extent that tests are particular modes of communication, they may be regarded as different languages.

These languages may be easier or harder for different subjects but it cannot be assumed that one language is necessarily more valid than another an intelligence scale, to be effective as well as fair, must utilize as many different languages (tests) as possible.

He pointed out the role of nonintellective factors at all levels of intelligence and inserted this note of caution: "Nonintellective factors are necessary ingredients of intelligent behavior; they are not, however, substitutes . . . for other basic abilities."

It should be noted that, over the years, Wechsler also found time to serve as Clinical Professor at the New York University College of Medicine, a Trustee of the American Board of Examiners of Professional Psychology, President of Division 12 (APA), and President of the American Psychopathological Association. He has had more than 60 articles published in scientific journals and is the author of *The Measurement of Adult Intelligence*. This book was first published in 1939. It went through three editions and, in its fourth edition in 1958, it became *The Measurement and Appraisal of Adult Intelligence*. A fifth and enlarged edition of this book, by Joseph D. Matarazzo, was published in 1972.

Although he retired from his position as chief psychologist at Bellevue Hospital in 1967, it is obvious to all who know him that he has simply "changed jobs." With writing, lecturing, traveling, developing new test ideas, and researching new areas, he has been busier than before. Among topics that have been of interest to him are artificial intelligence, the problem of memory storage, and collective intelligence. His views on the last are in his paper, "The Concept of Collective Intelligence," published in the *American Psychologist*, October 1971.

David Wechsler has made major contributions to psychology for more than a half-century. Hopefully, he will continue to do so for many years to come.

Gold Medal Award

The Trustees of the American Psychological Foundation invite members of the American Psychological Association to nominate candidates for the Gold Medal Award. The Award is given to an American psychologist in recognition of a distinguished and long-continued record of scientific and scholarly accomplishments. The Award is limited to psychologists 65 years of age or older and is also limited to those residing in North America. Nominations should be accompanied by a statement highlighting the accomplishments of the nominee. They should be addressed to: Secretary, American Psychological Foundation, 1200 Seventeenth Street, N.W., Washington, D.C. 20036, to be received no later than March 15, 1974. Decisions will be made by the Trustees of the Foundation.

American Psychological Foundation Awards for 1973

Gold Medal, Distinguished Contributions to Education in Psychology, and the National Media

On August 28, 1973, at the annual meeting of the APA in Montreal, the American Psychological Foundation announced the recipients of the Gold Medal Award, the Distinguished Contributions to Education in Psychology Awards, and the National Media Awards. The presentations were made by Henry W. Riecken, President of the APF. Harry F. Harlow received the Gold Medal Award; James B. Maas and Frank J. McGuigan were given the Teaching Awards; and Gerald Jonas, ABC News and Jules Power Productions, the Great Atlantic Radio Conspiracy, Christine Darg, and Elliott Aronson were the recipients of the National Media Awards. Other members of the APF are Nicholas Hobbs, Gardner Lindzey (Vice-President), Boris E. Chernay (Treasurer), George Miller, George Albee, William Bevan, Kenneth B. Little (Secretary), Kenneth B. Clark, and Anne Anastasi.

The American Psychological Foundation was established in 1953 to receive gifts from psychologists and others who wish to contribute to the advancement of psychology as a science and a profession in the service of knowledge and the welfare of man.

Harry F. Harlow

Gold Medal Award

Each year at the annual convention of the American Psychological Association, the Foundation presents its Gold Medal Award to a senior American psychologist in recognition of a distinguished and long-continued record of scientific and scholarly accomplishment. With the Medal goes a cash award of \$1,000. Past recipients of the Gold Medal Award are Robert Sessions Woodworth, Edwin R. Guthrie, Edwin G. Boring, John F. Dashiell, Walter R. Miles, Gordon W. Allport, Heinrich Klüver, Karl M. Dallenbach, Floyd H. Allport, Henry A. Murray, Sidney L. Pressey, B. F. Skinner, and Gardner Murphy.

HARRY F. HARLOW

This year's recipient of the Gold Medal Award has built a distinguished scientific career upon the study of basic psychological phenomena that are simultaneously of great scientific interest and great social importance. It is fair to say that, while he has been concerned with learning and behavior changes accompanying maturation from infancy to adulthood, and while he has shown some interest in therapeutic communities, a larger share of his attention has been given to affective behavior—especially to the affective relations between parents and offspring and to the pathologies of these relations. Although he would surely agree that "love is not enough," it

is clear that he believes love is in first place, and that whatever is second is quite a few furlongs back. He has lectured and written extensively on the insufficiency of love and is probably best known to the general public for his views on this topic. Indeed, numbers of American mothers may have been influenced in how they behaved toward their children by hearing or reading his views.

On the other hand, it is not true that he contributes a regular column to the *Ladies Home Journal*, although that is one of the few journals in which his work has not appeared. He generally reports his work in prose but has occasionally resorted to verse, perhaps because he thinks it helps him to make better contact with his subject. Finally, he does not work with human subjects, but only with their close relative, the rhesus monkey.

The facts of Harry F. Harlow's academic history are simple—almost defiantly simple for the purpose of constructing an exciting story. There are not a lot of comings and goings, changes of scene, or of fortune, but rather a record (rare among psychologists) of attachment to a single university that parallels his steadfast interest in the monkey. Harry Harlow was born in Fairfield, Iowa, long enough ago to make him eligible for the Gold Medal Award. After a year at Reed College he completed his university education at Stanford, where he received the BA and, three years later, the PhD in 1930. He immediately joined the psychology faculty at the University of Wisconsin and has remained a member of it ever since. He spent the 1939–1940 year as a Carnegie fellow in anthropology at Columbia University and spent two years as chief of human resources research for the Army in the early 1950s. Since 1956 he has held the George Cary Comstock Research Professorship in Psychology at Wisconsin.

But if his residential history is relatively tranquil, his scientific career is full of innovation, discovery, and invention. It is well known that he established at Wisconsin one of the earliest primate laboratories in the country. What is not so well known is that the establishment of that laboratory resulted from one of many fortunate accidents that Harry Harlow has known how to exploit to scientific advantage. Harlow had completed his doctoral dissertation at Stanford under Calvin P. Stone, running rats on elevated mazes, and he expected to continue this line of work. Upon his arrival in Madison he inquired the location of the animal laboratory, only to be told that it had been torn down the previous summer. The wife of one of his

colleagues, noting his dismay at this news, suggested helpfully that he go out to the Vilas Park Zoo and conduct his research on the monkeys there. He had never worked with monkeys or even seen one at close hand, but implausible as such a plan must have seemed to him, the young investigator explored it. The experience converted him because, as he later remarked, "monkeys were so much more broadly able than rats." His delayed-reaction-time experiments at Vilas Park Zoo were a success, and he set out to build his own facility.

In that early primate laboratory, Harlow began his 40-year scientific journey through the intricacies of rhesus psychology. He first undertook to investigate the learning ability of monkeys by studying the effects of lesions in specific cortical regions. One thing led to another. The learning research program required a large number of monkeys, so a breeding program was started. In order to reduce the incidence of contagious disease and to standardize the early experience of the subjects, baby monkeys were separated from their mothers a few hours after birth and reared in individual cages. The effect of this separation from mother began to be appreciated as Harlow and his colleagues noticed the strong attachment which infants developed for their cheesecloth baby blankets. A flash of insight led to the invention of the surrogate mother in 1957, and to the series of experiments on contact comfort. A marvelous bevy of surrogate mothers were constructed: mothers of terry cloth, hardware cloth, satin and silk; lactating mothers and dry ones; mothers with painted faces or merely bald knobs; heated and refrigerated mothers; mothers that rocked and stationary mothers. The trauma of tactile deprivation and the consolation of clinging led Harlow to an infatuation with skin. In his presidential address to this Association, he praised cutaneous contact throughout the mammalian world—in verse. Regarding the hippopotamus, he declaimed:

This is the skin some babies feel
Replete with hippo love appeal.
Each contact, cuddle, push and shove
Elicits tons of baby love.

The research on social attachment in relation to security and exploratory behavior led back again to learning, especially the infant's learning how to communicate and to play. Infant play, Harlow observed, is "the primary activity leading to effective age-mate love."

The varieties of love—maternal, infant, peer, heterosexual, and paternal—were a major theme in

his research for a decade after the construction of the first surrogate mother, although he never lost interest in the ability of rhesus to solve problems as well as to learn appropriate social roles. The significance of rearing in isolation became dramatically clear when "motherless" monkeys (i.e., females reared in isolation) themselves became mothers and displayed an appalling disregard for their offspring, ignoring them or even abusing them violently. Harlow also observed, in monkeys reared in isolation, the occurrence of something very like the anaclitic depression reported by Spitz and Bowlby on the part of human infants when separated from their mothers. Following this lead in a series of experiments took Harlow to the systematic study of depression in monkeys and, eventually, to ingenious attempts to relieve that condition, using monkey psychotherapists as well as heated surrogate mothers.

This summary is an altogether too superficial sketch of the adventures of a scientific argonaut, who has not yet found the golden fleece but has discovered that the skin you love to touch is mother's. The full account of the journey is available in the *American Scientist* for 1972, lucidly and modestly written and sprinkled with Harlowian aphorisms: "There is more than milk to human kindness"; "A mother's face that would stop a clock will not stop an infant." "There is only one social affliction worse than an ice-cold wife and that is an ice-cold mother"; and "Female beagles have warm and wondrous love affairs despite the fact that they are basically bitches." The story of his research is the story of his professional life—truly a quest for knowledge—knowledge which, as he says, "is forever changing" and hence "the search for knowledge never ends." It is a story plainly told by a plain-spoken man who takes his task with the utmost seriousness but takes himself with a measure of humor and is utterly without pretension. He knows and acknowledges the role chance plays in scientific discovery and we recognize, as we follow his progress, the role played by a prepared mind.

Harry Harlow's scientific bibliography is appropriately lengthy, as is his list of distinguished students. He has served psychology in other ways as well. Besides the presidency of APA in 1958, he has presided over the Midwestern Psychological Association and the Division of Experimental Psychology. He edited the *Journal of Comparative and Physiological Psychology* from 1951 to 1963, al-

though he claims that the real work was done by the late Margaret Kuenne Harlow.

This year's recipient of the Gold Medal has been honored before—many many times. He was given the Distinguished Scientific Contribution award by this Association in 1960. He won the Warren Medal in 1956, and received the National Medal of Science from Lyndon Johnson in 1967. He is a member of the National Academy of Sciences, the American Academy of Arts and Sciences, and the American Philosophical Society. To this man so often honored, with honors richly deserved, the American Psychological Foundation is proud to award its Gold Medal, together with a check for \$1,000 and a scroll whose citation reads: "To Harry F. Harlow—a creative scientist and dedicated investigator, he has enlarged the science of man through artful experimentation with monkey."

Distinguished Contributions to Education in Psychology Awards

The American Psychological Foundation has also been accustomed to recognize and reward distinguished contributions to education in psychology. These awards are given to individuals who have made unusual contributions to instruction in psychology either through their own teaching or through other instructional functions such as developing new curricula. The award is a check for \$1,000 to be used for the improvement of education in psychology in whatever manner the awardee may decide, and a citation indicating the nature of the contribution. Two awards are being made this year on the basis of recommendations by the APF Committee on Teaching Awards which was chaired this year by Jay Knopf.

JAMES B. MAAS

James Maas received his bachelor's degree from Williams College and his master's and doctorate degrees from Cornell University. He became an assistant professor of psychology at Cornell in 1965, where he has continued. He has recently accepted the position of Director of the Center for Improvement of Undergraduate Education at Cornell.

In 1972 he received the Clark Distinguished Teacher Award at Cornell University. He is singled out as a recipient of this APF award because

James B. Maas

of his total and outstanding commitment to undergraduate teaching and for the innovative development of methods, procedures, and materials for the teaching of large numbers of students.

At the present time, Maas is teaching in the introductory psychology program that has a classroom enrollment of 1,300 students per term. Student ratings of this program place it at the highest rank in the University. A major feature of this course is the creative utilization of multimedia presentations which have been in large part developed by Professor Maas. He devised a slide program for general psychology which has been adopted by more than 1,200 colleges and universities, and a series of other formats which have been in great demand and use. He developed the Cornell Inventory for Student Appraisal of Teaching which is being used at over 300 universities. He has imaginatively used "candid camera" episodes in the teaching process. He introduced at Cornell a graduate seminar in the teaching of psychology. These innovations demonstrate his commitment to excellence in teaching and extend his influence on the development of future teachers.

James Maas delivered at this Convention his presidential address to Division 2 on the subject of educational innovation—an interest that is reflected in the citation which accompanies this award: "To James Beryl Maas—whose style and ingenuity in teaching have suggested imaginative ways in which media technology can be introduced effectively. He has amply demonstrated significant educational effects in traditional classroom settings."

FRANK JOSEPH MCGUIGAN

Frank McGuigan received both his bachelor's and master's degrees from the University of California, Los Angeles, and his doctorate from the University of Southern California in 1950. His academic career began at the University of Nevada from which he moved to become a research scientist for five years at the Human Resources Research Office. He took up teaching again at Hollins College, Hollins, Virginia, in 1955 as professor and chairman of the Department of Psychology, where he has been ever since. His selection as recipient of this award is in recognition of his long-standing dedication to scholarship, to the promotion of teaching excellence in a small liberal arts college, and to the implementation

Frank J. McGuigan

of quality education in psychology through his own example.

Under his leadership, the Psychology Department of Hollins College became recognized for producing students who have gone on to take advanced degrees in psychology. Professor McGuigan has written several effective undergraduate texts. He has been active in the evaluation of teaching in a number of educational settings ranging from grammar school through the university level, as well as adult education programs. At Hollins College, he began early to encourage the involvement of qualified undergraduates in collaborative research with faculty members. He proposed and developed a master's program at Hollins, concentrating on preparatory work for the PhD. Since its inauguration in 1958, 89 out of 134 students have entered into PhD programs around the country. Letters from former students uniformly attest to his outstanding classroom performance as "challenging and meaningful." He consistently has been able to attract faculty of the highest quality in both research activities and teaching excellence.

His citation reads: "To Frank Joseph McGuigan—A successful teacher and scholar, because he is, first, a genuinely zealous student of psychology and a powerful source of inspiration in deed and word to those who have worked with him."

National Media Awards

These awards are offered as a means of recognizing and encouraging the communication of psychology to the general public by reporters, magazine and free-lance writers, television, radio, films, and books. Awards are presented in six categories (only five awards were made this year, however, and next year the television and film categories will be combined). In addition, a Grand Prix winner is selected from the winners of the five categories. Each winner received three days' expenses to the APA's Annual Convention in Montreal and a citation. A record total of 162 entries were received in the six categories this year.

The first winner of the Grand Prix award was Gerald Jonas for his two-part series on the work of Neal Miller which appeared in the August 19 and 26, 1972, issues of the *New Yorker* magazine. Jonas also received the award in the magazine category.

Other winners included: *Television*—"The Masks We Wear," produced by ABC News and Jules

Power Productions, narrated by Harry Reasoner; *Radio*—"The IQ Fallacy," produced by the Great Atlantic Radio Conspiracy and aired on WBJC-FM in Baltimore, Maryland; *Newspaper reporting*—Christine Darg of the *Richmond Times-Dispatch* for a series of articles on the human potential movement; and *Books/monographs*—Elliott Aronson for the book *The Social Animal* published by W. H. Freeman and Company.

In addition to the five winners, honorable mentions and letters of special commendation were awarded to a number of entries in all six categories.

1. In the newspaper reporting category, honorable mentions were awarded to Margaret Deats Bott for a series of articles in the *Galveston* (Texas) *Daily News* on mental health; Tom Darcy, a political cartoonist for *Newsday* (Long Island) who wrote an autobiographical account of his battle against mental illness entitled "After the Recovery, Years of Judgement"; Duston Harvey, a staff writer for *United Press International*, for an article entitled "Controversy Over Black Vs. White Intelligence Rages On"; Barbara Katz, a reporter for the *National Observer*, for the article "Finding Psychiatric Help Can Be Traumatic Itself"; and Paul Kidd, for a series of articles in *The Spectator* (Hamilton, Ontario, Canada) on "Mental Health in Hamilton." Tomi Knaefler, a reporter for the *Honolulu Star Bulletin*, received a letter of commendation for her coverage of the APA Annual Convention in Honolulu last year.

2. In the books/monographs category, honorable mentions were awarded to Robert E. Ornstein for *The Psychology of Consciousness* published by The Viking Press (New York City); and to James Leslie McCary for *Human Sexuality* published by Van Nostrand Reinhold Company (New York City). Hilde S. Schlesinger and Kathryn P. Meadow received a letter of special commendation for *Sound and Sign: Childhood Deafness and Mental Health* published by the University of California Press (Berkeley).

3. In the magazine writing category, honorable mentions were awarded to Kenneth Goodall for "Shapers at Work" which appeared in *Psychology Today* magazine and to Philip Zimbardo for "Vandalism: An Act in Search of a Cause" which appeared in *Bell Telephone* magazine.

4. In the television category, an honorable mention was awarded to "The Lee Phillip Show" which appears on WBBM-TV in Chicago. A letter of special commendation was sent to Matt Duncan for

a special introductory course devised for educational television in Southern California entitled "As Man Behaves."

5. In the radio category, honorable mentions were awarded to Connie Goldman of KSJN radio in Minneapolis, Minnesota, for "Margie Talks About Death and Dying" and to Carol Kadushin of National Public Radio for a series of shows entitled "It's All in Your Mind."

6. No film winner was selected, but a letter of special commendation was sent to Richard I. Evans of the University of Houston for the film *Psychology of Creativity*.

The National Media Awards program was established by the American Psychological Foundation in 1956 to honor outstanding reporting on psychology in the national media. The 1973 winning entries were produced sometime between May 1, 1972, and May 1, 1973.

Announcement by Henry Riecken of the Rosen Bequest

Finally, I would like to take advantage of this occasion to make a special announcement. It is the sort of announcement that gives the President of the American Psychological Foundation a special pleasure, for it concerns an opportunity to expand and deepen the Foundation's program in psychology.

At the meeting this morning, the Trustees accepted with gratitude the bequest of Esther Katz Rosen. In her will, Dr. Rosen made the American Psychological Foundation the residuary beneficiary of her estate, to be used "for the advancement and application of knowledge about gifted children," giving the Trustees fairly broad discretion in interpreting those terms. The size of the Esther Katz Rosen fund is not yet precisely known since the estate is still being settled, but the bequest is a substantial as well as a generous one.

Esther Katz Rosen, who died at the age of 77 last April 13, was a practicing clinical psychologist as well as a civic leader in Philadelphia for more than 35 years, specializing in work with children.

She was a former member of the Board of Examiners of the Pennsylvania Psychological Association and a former secretary of that state association as well as a fellow of APA. Dr. Rosen was educated at Goucher College and received both an MA and PhD from Teachers College of Columbia University, where she was a Runyan Scholar as well as an assistant to Edward L. Thorndike at the Institute of Educational Research. She was also a diplomate in Clinical Psychology of the American Board of Professional Psychology. A consulting psychologist in private practice in Philadelphia, she specialized in diagnostic evaluation and guidance with children and youths as well as offering advisory services to parents. She was, at the same time, active in Philadelphia civic affairs, serving on the Philadelphia County Board of Assistance, the Association for Jewish Children, the Crime Prevention Association, and various committees of the Health and Welfare Council of the City. She was an ardent believer in civil rights and a worker for equal rights for women. Those who knew her personally speak with great warmth and affection of her lively curiosity, her sense of humor, and her vibrant personality. In writing about Dr. Rosen, one of her nieces concluded with this remark: "Her love and understanding of children was very deep and she left her bequest to the American Psychological Foundation because she had confidence that it would use the funds wisely in accomplishing her objectives for gifted children."

The Trustees are very much aware of their responsibility to use these funds wisely, and have begun a deliberative process that will probably extend over some period of time before a conclusion is reached as to the best way of using the Esther Katz Rosen Fund for its founder's purposes. The Trustees would like to draw on the wisdom and the advice of members of the APA and have asked me to make known their willingness to receive your suggestions about the best ways of advancing and applying knowledge about gifted children. I hope that if you have any thoughts along this line that you will write to the President of the American Psychological Foundation in care of the American Psychological Association in Washington, D.C.

Comment

Some Comments on Hersch

As this comment is essentially a criticism of "Social History, Mental Health, and Community Control" (Hersch, August 1972), it is appropriate to review briefly the article. Hersch sees the mental health movement as being in a "kinship relationship [p. 749]" to the other movements of the 1960s, with the mental health movement reflecting an environmental reform point of view. He discussed shifts in ideology that he thinks have occurred: (a) from a traditional, clinical frame of reference to a public health frame of reference, and (b) the addition of social action ideology to the preceding frames of reference. The social action ideology resulted in the involvement of mental health professionals in community control. Unforeseen problems of community control resulted in professional and personal difficulties for those mental health workers who tried to function within the community control framework. After his analysis of these difficulties, Hersch concluded that "it would be unfortunate if we should prematurely reject the community control principle because we lacked the facility and skills for working within it [p. 754]."

Hersch's analysis was based on the assumption that the growth of the mental health movement and the subsequent involvement of mental health professionals developed from a desire to implement democratic and humanistic principles. This assumption is fundamentally in error, with the result that his analysis contained a series of errors that developed as a consequence of his initial assumption. It is a fundamental error because it ignores the social unrest and developing power struggle of the 1960s. Ignoring these social and political realities in an attempt to analyze the development and difficulties of community control, a

social phenomena whose very development is a part of these same realities, leads to conceptualization and analysis that does not deal with critical issues. Only ignoring the social and political realities of the 1960s could result in the error to be discussed in the next paragraph.

Writing in 1972, after Watts, Detroit, and Newark, Hersch discussed the anger encountered by mental health professionals working within community control. This anger, coming from the local residents, directed toward the professionals, was described in this way, "it is as if there is the emergence of a deep-seated and long-standing anticolonialist rage [p. 753]." To describe this rage on an as-if basis reflects a refusal to deal with the full reality of the lives of the oppressed and the disadvantaged. One might as well try to analyze Watts, Detroit, and Newark with "as if"!

As a basis of discussing the incorporation of a social action ideology into the community mental health movement, Hersch defined social action. His definition derived from his original position of democratic and humanistic principles with the thrust of social action being for "the well-being of the population or community as a whole [p. 750]." In his definition he omitted the following crucial characteristics of social action: (a) Social action is contingent upon the existence of pressure groups desiring a change in their organizational and/or political environment; (b) pressure groups can only effect change as a function of the power they exert; (c) desired change may range from modifying and limiting to destroying the particular power structure involved; (d) the results of a social action approach may not benefit the larger society; and (e) social action has a potential for destruction. It follows logically from these characteristics that the realities of the social action

arena are contest, bargaining, conflict, confrontation, threat, and violence. The professional mental health workers did not understand social action in these, or similar, terms and encountered unexpected difficulties. Those who understand social action in these terms would encounter difficulties but not those developing from unanticipated or unrecognized realities. It is obvious from the problems with which they struggled that the mental health professionals were not knowledgeable of, let alone skilled in, social action. Hersch recognized that the professionals were not prepared for the problems that developed in community control situations, and he offered an explanation. His explanation, however, did not provide a basis for avoiding future errors. It could very well be considered a sophisticated rationalization:

Perhaps out of a reawakened awareness of democratic principles, perhaps out of frustration for the failures of the past, perhaps out of a sense of collective guilt—for whatever mix of reasons, there was a rush to community control to provide the answers that were not available before [p. 752].

Using an inadequate definition, Hersch proceeded to discuss the incorporation of the social action ideology into community mental health. He sees a shift from providing helping services to "consumer groups" to programs for promoting the political power of these groups. Consistent with his basic assumptions and previous errors, he used the concept "consumer group" for the disadvantaged. This is, again, an error that derives from the lack of recognition of the social and political realities. The crucial characteristic of a "consumer group" is that it has purchasing power—the ability to decide what, when, and where it will purchase. A recipient group has the needs for services but lacks the purchasing power. The disadvantaged have been recipient groups, not con-

sumer groups. To describe them as consumer groups is to ignore their essential powerlessness. If there is no recognition of the fact of powerlessness and the conditions that make for powerlessness, there can be no anticipation of the problems that will occur when a group attempts to change from powerlessness to holding some degree of power. This was one of the sources of difficulty for the mental health professionals involved in community control.

Hersch's analysis of three problems in community control was consistent with his preceding analysis in that he continued to ignore social and political realities. The problem of the undemocratically selected, pathologically motivated leader is discussed in terms of personal dynamics. Having labeled these leaders diagnostically in terms of their pathology, he has implicitly laid the basis for either emotionally dismissing them as leaders, or rationalizing anger toward them. He did not include in his analysis the fact that pathological or not, undemocratically selected or not, these leaders must be dealt with in the context of their role in the community.

The second problem of community control that concerned Hersch was that power is "often not wielded for the sake of the rational development of the program [p. 753]." At the risk of sounding cavalier, our own personal reaction to this was "so what else is new?" Middle-class professionals experienced in the use of such power have been known to misuse it. Hersch acknowledged this in his statement,

Now it is true that the professional community had frequently failed to assume its responsibilities where the disadvantaged were concerned. Where it did take responsibility, it often did so on its own terms, and therefore inappropriately, if not destructively [p. 752].

(Having clearly diagnostically labeled the pathological leader, we cannot understand why Hersch did not analyze the behavior of the professional community in the diagnostic terms of *character disorder*.)

The third problem dealt with by Hersch was that of the anger of the local residents toward the professionals. He correctly described the ways in which the rage is expressed and the effects of these expressions of rage. Inasmuch as he dealt with this rage as previously indicated, on an as-if basis, he denied the valid basis for this rage. He cannot, therefore, recognize that the middle-class mental health professionals are the representatives of the larger society responsible for the conditions engendering the rage. Not too surprisingly, he continued by acknowledging that the aforementioned problems are not exclusive to low-income community control boards (excluding the rage problem), but stated that they are more frequent and vivid with low-income boards. The acknowledgment does not, however, proceed to ask the most important question: If these problems do occur with middle-class boards, and professionals function on and with these boards, why did the occurrence of this problem behavior by lower-class board members take the professionals by surprise?

In referring to the people who encountered all of these difficulties and reacted with a "kind of professional backlash [p. 752]," Hersch was willing to say, "The fault was their own It was folly, of course, to expect that greater nobility, deeper wisdom, and less human frailty would be found among the poor than among the well-to-do [p. 754]." He offered as an explanation for this mistaken behavior "their idealism and zest for the new . . . [p. 754]." Idealism and a desire for novelty are hardly an adequate explanation for inadequate behavior by a group of professed experts. The professionals went into community control activity, ignoring the social and political realities, ignoring the history that preceded them, and ignoring the fact that they are part of a larger society which is primarily responsible for this very history. They were unaware of the fact that they were equipped with only their good intentions and became angry

when their good intentions were spurned. This is the behavior of elitism, benevolent in intention, but nonetheless elitist, and Hersch, again, did not indicate this as part of his analysis.

Was This Article Necessary?

It is unfortunate that the *American Psychologist* chose to give the unopposed impact of primacy and prominent location to a sweeping, unqualified negation of an entire area of behavioral science, namely, intelligence testing (McClelland, 1973). No doubt those who seek any available support for their antagonism to testing will gladly accept the apparent conclusion that nothing about testing is positive and that it remained for the January 1973 issue of the *American Psychologist* to make this known.

Among the observations that could be made about the article are these:

Logically, the first and most interesting result of the McClelland contribution should be a skeptical review of the author's own distinguished studies in the field of achievement. Portions of them are based on techniques similar to those involved in the standardization of intelligence tests. They depend, in fact, partly on projective techniques, whose validity has been questioned even more than that of intelligence tests.

The large number of employees of the Educational Testing Service as well as the estimable nature of its earnings are referred to as if these were comments on the correctness of the organization's work. The effect of their tests, "which have tremendous power over the lives of young

people by stamping them 'qualified' and 'less qualified' for college work [p. 1]" would suggest the evil intent of some Boris Karloff-like character in charge. Are these allegations germane to the adequacy of tests?

"Tests predict grades in school," it is stated, "because the games people are required to play on aptitude tests are similar to the games teachers require in the classroom [p. 1]." Far from being a detractor from such tests, there could hardly be a greater compliment. The question here is society's current approval of classroom "games" as a proper criterion. If that criterion is judged unacceptable, it should be changed, after which the predictors would require adjustment. Clearly, the game playing referred to and so strongly condemned by the author is a prime example of criterion sampling. A remarkable contradiction appears when a later passage stresses precisely the point that "the best testing is criterion sampling [p. 71]." In any event, the study of job behavior as a source of test items has been described in the literature for years. It is, and has been for over a generation of students, an elementary part of their education in test techniques.

Further reference to the criterion issue is offered in the statement that

even a little criterion analysis would show that there are almost no occupations or life situations that require a person to do word analogies, choose the most correct of four alternative meanings of a word, etc. [p. 7].

Here, the well-known fact that test items often relate indirectly to the criterion is overlooked. They need not have face validity.

Selective emphasis of data is apparent in the presentation of Thorndike and Hagen as "good guys" because they did not find encouraging correlations between scores and later success. On the other hand, the statement that "most psychologists think so," referring to general confidence in this type of prediction, is promptly minimized (p. 3). It should be added

that although the Thorndike and Hagen predictions were by no means positive in all respects, they did uncover correspondence between the type of work in which the subjects were employed and tests taken at an earlier time.

In one portion of the article the reader is warned that "We know that correlation does not equal causation, but we keep forgetting it [p. 3]." Is there a suitable text or qualified teacher who has not included this caution in an early stage of instruction?

Is it really necessary at this late date to become intensely concerned about the theoretical aspects of the "role of power in controlling life-outcome criteria [p. 4]"? The part played by culture in behavior of all kinds, including adaptable behavior, has caused spasms of breast beating and abject cries of confession by so many psychologists and for so many years that surely we would administer the death blow of boredom to students by offering the thought as a scoop in 1973. Is it really a fact that large numbers of psychologists in the test field spend their time in "their offices where they play endless word and paper-and-pencil games," when they should "go into the fields where they actually analyze performance into its components [p. 7]"? If there is actually one psychologist who does fit this description, he exemplifies the uninformed person's stereotype of the armchair psychologist who arbitrarily makes up test items without validating them. Apparently, McClelland does not understand standardization, the basic factor in test construction.

Finally, the view that intelligence tests directly measure innate qualities has been of historical interest alone for decades. Nevertheless, it was thought necessary to state that "stability is supposed to mean that the score reflects an innate aptitude that is unmodified by experience . . . [p. 8]." It would be a challenge to locate more than an isolated few who take this stand today.

The old slogan is reversed: Emphasize the negative and forget the positive.

McClelland on the Terman Data

McClelland (1973) argued that psychometricians have overemphasized intelligence, as measured by IQ tests, and that they should devote more effort to the development of tests allowing the prediction of competence in specific vocational categories. Most of his major points seem well taken. However, one can argue with his interpretation of the data from Terman's studies of genius. The major thrust of a large portion of McClelland's presentation came from his analysis of the Terman data. Further, McClelland's comments concerning the relations between parental socioeconomic advantage and children's success in the Terman studies of genius have relevance to the recent spate of papers speaking to the same general issue. Therefore, it appears useful to examine the Terman data, especially those reported in the first (1925) and fifth (1959) volumes devoted to Terman's study of genius, in order to determine the degree to which a close examination of these data supports McClelland's interpretation of them.

McClelland (1973) wished

to state, as emphatically as possible, that Terman's studies do not demonstrate unequivocally that it is the kind of ability measured by intelligence tests that is responsible for (i.e., causes) the greater success of the high-IQ children. Terman's studies may show only that the rich and powerful have more opportunities, and therefore do better in life . . . By current methodological

standards, Terman's studies (and others like them) were naive. No attempt was made to *equate for opportunity* to be successful. His gifted people clearly came from superior socioeconomic backgrounds to those he compared them with (at one point all men in California, including day laborers). He had no unequivocal evidence that it was "giftedness" (as reflected in his test scores) that was responsible for the superior performance of his group. It would be as legitimate (though also not proven) to conclude that sons of the rich, powerful, and educated were apt to be more successful occupationally, maritally, and socially because they had more material advantages [p. 5].

Terman's gifted group did come from an economically advantaged group. Possibly, in a moderately open society, one would expect those parents who have genes disposing themselves and their offspring toward brightness, as measured by IQ, to have done better economically than the population at large. Presumably, to "equate for opportunity," one would find parents similar to the parents of the gifted in education, stability, initiative, etc., who were day laborers. This might be a hard group to find, assuming that social mobility does occur and is, in part, a result of attributes of the individual. How advantaged were the parents of Terman's gifted sample? If scoring well on IQ measures is a consequence of environmental advantages resulting from superior socioeconomic status (McClelland, 1973, p. 6), then we can compare the offspring of the gifted group with the gifted group itself. The proposed examination will tell us a bit about how much effect environmental advantage has on such attributes as IQ; about the degree to which *pull* (McClelland, 1973, p. 4) is involved in vocational success.

The mean IQ of Terman's gifted group was 151 (Terman, 1925, p. 45). Various ways were used to categorize the parents of the gifted. One categorization (p. 62) gave the following information concerning the occupations of the parents of the gifted: professional, 29.1%; com-

mercial, 46.2%; industrial, 20.2%; and public service, 4.5%.

Another measure of the occupational status of the parents of the gifted was obtained through the use of the Taussig Scale, which more closely resembles the Minnesota Occupational Scale, which was used to measure the occupational status of the gifted group themselves. This scale provides the following information: professional (similar to Group I, Minnesota Occupational Scale), 31.4%; semiprofessional, higher group (Group II, Minnesota Occupational Scale), 31.2%; lower group (Group III), 18.8%; skilled labor (Group V),¹ 11.8%; semi-skilled labor (Group VI), 6.6%; and unskilled (Group VII), 1.3% (Terman, 1925, p. 64). A third analysis led Terman (1925) to state that "the mean of 12.77 for total fathers of gifted corresponds to the Barr² rating of a stenographer, librarian in a small city, or primary teacher [p. 71]." Of the parents of the gifted sample, 35.3% had family incomes below that of the average of skilled laborers in California at that time (p. 72). All in all, there seems to be no great amount of *pull* on the part of the parents of the gifted. They are not as "rich and powerful" as McClelland suggested.

The gifted offspring themselves were studied last in 1955 (Terman & Oden, 1959). Data concerning IQ (but not occupation) were obtained from the offspring of the gifted sample. It is clear that the offspring of the gifted grew up in better socioeconomic circumstances than did the gifted group themselves. Among the gifted males, 86.3% were in Classes I or II of the Minnesota Occupational Scale (p. 74). Of the employed gifted women, 65.1% were categorized as professional persons (p. 87). Of the husbands of the gifted women, 73.9% were in Categories I and II of the Minnesota Occupational Scale (p. 138). Only 15.5% of the wives of

¹ Group IV, in the Minnesota Occupational Scale, is an agricultural group.

² Another system of occupational rating.

gifted men were employed. Of those employed, 56% were categorized as professional persons. The mean family income of the gifted was \$10,866, at a time when the mean family income of the urban white population (itself a higher than average income group) was \$5,069. Only 6% of the gifted had incomes below \$5,000 (pp. 100-101).

The gifted were more successful than their parents. If "getting a high IQ" results from socioeconomic advantages, the children of the gifted should score higher than their gifted parents. They did not: The mean IQ for both male and female offspring is 132.7. This is well over one standard deviation lower than the scores of the gifted parents. The spouses of the gifted parents were tested with the Concept Mastery Test, not the Stanford-Binet, and no IQs are reported. However, the occupational levels of the spouses of the gifted are similar to the occupational level of the gifted of their respective sexes. The Concept Mastery Test scores of spouses (Terman & Oden, 1959, pp. 56-60) suggest that the mean IQ of spouses, had they been tested with a test yielding an IQ, probably would have been above 120 at the least, since the spouses did a bit better than a comparison group of electronic engineers and scientists (p. 60). The midparent IQ of offspring of the gifted probably is between 135 and 140; the occupational level of the gifted is high, as compared with that of the parents of the gifted. Yet, the IQ of the children of the gifted is lower than that of the gifted themselves or of the mean of gifted and spouses of gifted. This result would be expected from a genetic interpretation of giftedness—in fact, this is what Galton suggested long ago (e.g., Galton, 1892, p. 74) and might be expected in any situation involving polygenic inheritance. The regression toward the mean in IQ (Galton's "Law of Filial Regression") cannot easily be explained in terms of environmental advantage leading to skill at taking IQ tests, because the gifted provided a sub-

stantially more superior environment for their offspring than that which they themselves received. We have no data concerning the degree to which parental "clout" influences the occupational outcomes of the offspring of gifted parents. The fact that parental environment input did not lead to an increase in tested ability (although it may have reduced the expected regression toward the mean) suggests that the effects of parent education and parent income and of *pull* on performance are not as great as McClelland posited. I suspect that all of us will agree that environmental advantage and *pull* are helpful. The question is, Does advantage account for the preponderance of the variance in IQ and *pull* for much of the variance in occupational success, as McClelland suggested as an alternative explanation to that of Terman? It seems doubtful that such is the case.

RONALD C. JOHNSON
University of Hawaii

On McClelland's "Testing for Competence . . ."

Some statements in McClelland's (1973) article need to be drawn from his polemic and examined with care, otherwise the reader may get the impression that he really does not mean his disclaimers, such as "I do not want . . . to dismiss intelligence tests as irrelevant or unimportant . . . [p. 5]." For example, note the statement that

while grade level attained seemed related to future measures of success in life, performance within grade was related only slightly. In other words, being a high school or college graduate gave one a credential that opened up certain higher level jobs, but the poorer students in high school or college did as well in life as the top students [p. 2].

It is reasonable to ask why McClelland neglected to point out that grades might have something to do with the achievement of the credentials? While many things may enter into school completion patterns, including all of those social factors we are concerned about, did McClelland want us to believe that grades (which correlate with IQ and achievement tests) do not correlate with the amount of schooling one gets? In his example that followed, to show that grades do not predict success in later life, McClelland completely neglected to point out that the groups examined may have been highly selected already. By whatever selection procedures were operating, are we to believe that Wesleyan University students were not selected into that University because they had "potential" as demonstrated by some prior performances? This might make likely the surprisingly high success of his group of students with averages of C- or less. But, *surprising* is not a strong enough word for his finding that the low group had lawyers, doctors, research scientists, and college and high school teachers (in a sample of eight); *incredible* would be more appropriate, as I find it hard to believe, retrospectively, that in those days Wesleyan University had such magic that students with C- or less would get accepted to medical, law, and graduate schools. In those days, you were not even granted a degree with less than a C- average in most places. But possibly my memory of the time is poor, which is not the point. The point is that somehow McClelland has conveniently neglected to mention that some selective processes have already occurred by the time people reach a given level, such as college graduate, and the majority of these survivors may well be able

to learn more and be successful in a wide range of occupations. Doesn't this have something to do with the difficulty in relating grades with his criterion of subsequent success?

Then, his rhetoric may bother one in its implications. "One would think that the purpose of education is precisely to improve the performance of those who are not doing very well [p. 2]." This surely can be one purpose, but please, is it okay if we also suggest some attention for those who are doing reasonably well and even for those who are doing very well as part of the purpose?

There is also the element of the implicit cultural conspiracy of which we are all obviously a part. "For the tests are clearly discriminatory against those who have not been exposed to the culture, entrance to which is guarded by the tests [p. 7]." "Until recent 'expectations' were made (over the protest of some), the tests have served as a very efficient device for screening out black, Spanish-speaking, and other minority applicants to colleges [p. 1]." But it seems that some "groups" do well with the tests and grading system. Possibly we have to suspect that all of the time, Jews, Japanese, Chinese, maybe Americans, and a few others have been the dominant element of the power elite bent on maintaining itself in this society.

If we are concerned with the problems of education, are we automatically supposed to respond favorably to such nonsense? There are some interesting and potentially useful suggestions for improving the system, including some that McClelland mentioned in the course of his article. The kind of nonsense he advanced with his presentation distracts from our attention to these.

EDGAR F. BORGATTA
Queens College of the
City University of New York

McClelland Replies:

In writing my article (McClelland, 1973), I consciously chose to write in a challenging, emphatic style, for the very simple reason that I had said many of the same things in *Talent and Society* over 15 years earlier in a sober and cautious way, and as far as I could determine no one paid the slightest attention (McClelland et al., 1958). For that matter, others like Cronbach in his excellent text on testing have also said many of these things in a less provocative way, and still the testing movement has marched on totally unmoved by logic or research evidence. Yes, Dr. Tyson (1974), textbooks regularly state that correlation does not equal causation, but that does not stop the testing profession from arguing that because the average IQ score for stockbrokers is higher than for carpenters, it takes more intelligence to be a stockbroker than a carpenter. I thought it might be at least worth trying to stir up things a bit and get people thinking a little harder about what they were doing. In so doing, I tried to be careful even though provocative, but obviously my commentators were so provoked that they couldn't notice the cautionary remarks or felt they were obviously inconsistent with what I "really" thought. I see little point in extending the discussion of what I did or didn't say, did or didn't mean. I'd rather put the energy into developing the new kinds of tests I think we need, and I hope others will do likewise.

But I certainly was pleased that someone was stimulated to start looking at Terman's data from the point of view I was urging. That was precisely the kind of outcome I hoped for from my article. Yet Johnson (1974) simply could not believe that I meant what I said in stating that "it would be as legitimate (though also not proven) . . . [p. 5]" to argue that pull accounted for the success of Terman's gifted group. He felt I must have meant that pull accounted for more, or

perhaps all, of the results. The fact is I have no prior conception of how the results would come out, except that I would be very surprised if both heredity and environment didn't contribute something to success. I was merely pointing out that Terman, and those who cite him, regularly fails to mention pull even as a possible source of variance in success.

So any attempt to begin to shed light on this problem is to the good, though I found Johnson's analysis rather incomplete. What would seem to be called for is (a) a comparison of the success of persons with high IQ from families with high and low socioeconomic status and (b) eventually something like a stepwise regression for predicting success based on such variables as status of parents, IQ, etc. In such a design it is possible to estimate the contribution of each factor to the outcome. If Johnson or anyone else has access to the original Terman data, I should think it would be very valuable to carry out such a reanalysis of the data.

Only one other factual point seems at issue. Borgatta (1974) simply doesn't believe the data I reported on students at Wesleyan University. I would be glad to send him the names of the people, their grade averages at Wesleyan, the names of the medical and law schools they got into, etc. What he perhaps forgets is that such students with poor averages could still, in those days, get into southern medical and law schools—fortunately for society, since many of them turned out to be quite distinguished—particularly if they served in World War II. His point about college graduates being selected already is well taken, even though their grades are terrible, but (a) that doesn't deal directly with the fact that we improperly use grades among this selected group to decide who should get into the professional schools and (b) it would be a more impressive point, if it didn't hold also for grades in high school, when the degree of selectivity is

much less. Grades in college or in medical school have very little connection with success as a medical specialist, educator, or general practitioner (see Taylor et al., 1965). Grades in high school have very little value for predicting various measures of life success (see McClelland et al., 1958). It really is worth reading the literature in this area; you would be surprised, Dr. Borgatta; I was, when I first read it.

A Voice from the Field¹

Harris (March 1973) cited studies and made observations concerning Peace Corps problems of selection, self-assessment, attrition due to non-selection factors, the need for conditions of moderate stress during training, and the need for both volunteer and staff evaluation in the field, which are in agreement with the author's own personal views, derived from field experiences and relevant research. Harris is to be commended for the emphasis of his

¹ The substantive content of this comment is based on the author's personal experiences and participant observations in the field as a Peace Corps

studies in this area and his plea for building the science of selection on a strong foundation of field-oriented research. However, at the same time, it seems to the author that he implied that if this type of research were not conducted within a Peace Corps context, then it could not be validly generalized to specific Peace Corps problems nor be used to support the psychologist's role when challenged by a new administration.

This may not have been Harris's intent, but his failure to cite literature which the author finds relevant to the general problem of selecting young civilian adults for service in a remote environment to which they have not previously been exposed supports this conclusion. Furthermore, in view of the recent comments on commitments to field research discussed by Fried, Gumpfer, and Allen (1973), Harris's apparent neglect of related studies appears to be at odds with his thesis advocating

field-oriented research. It should be noted that the Peace Corps and its successor, ACTION, are not unique as volunteer organizations but do hold the distinction of being the largest and most widely publicized. Numerous volunteer programs exist and often duplicate Peace Corps activities. The U.S. International Volunteer Service (IVS) program, the British Volunteer Service Overseas (VSO) program, the New Zealand Volunteer Service Abroad (VSA) program, and other similar programs offer examples. All have some form of selection procedure, although they may not have been studied and documented. Nevertheless, the International Secretariat for Volunteer Service (ISVS) has published reports in this area (e.g., Denny, 1966; Quarumby & Quarumby, 1969; and Taylor, 1969c). In another area, a number of evaluative and research reports are available which address the problems of both civilian and military volunteer selection for service in the Antarctic as well as the adaptation and performance of the volunteer in the field (a representative partial listing includes: Doll, Gunderson, & Ryman, 1969; Gunderson, 1965, 1968; Gunderson & Kapfer, 1966; Gunderson & Nelson, 1963, 1964, 1965a, 1965b, 1966; Gunderson & Ryman, 1971; Law, 1960, 1963; Mullin, 1960; Nelson, 1963; Palmaj, 1963a, 1963b; Seymour & Gunderson, 1971; Smith, 1961, 1966; Smith & Jones, 1962; Taylor, 1969a, 1969b; and Taylor & Shurley, 1971).

After having been selected for, and served, in both the Peace Corps and Antarctic programs, the author feels that there is a considerable overlap in the following areas: (a) selecting civilians for these programs, (b) the problems the volunteers will face in the (remote) environment, and (c) the type of individuals who volunteer. Antarctic volunteers are often young technicians, recent college graduates, or graduate students who apply for a year-long winter assignment. At least one psychologist (A. J. W. Taylor) has been active in

selecting both New Zealand VSA and Antarctic volunteers. The U.S. Antarctic Research Program (USARP) is of particular interest in this area because the final word on civilian selection remains with the university department or government agency sponsoring the individual. Thus, it is often possible to obtain field performance data on individuals who may not have been entirely acceptable to one of the psychologist-psychiatrist teams that screen all USARP winter-over volunteers.

Harris chose to focus on the Peace Corps psychologist's role as selection officer and the often neglected role of researcher. He lamented the passing of both of these roles, but in so doing appeared to neglect a major argument for the retention of the Peace Corps psychologist. With an overall attrition rate exceeding 50%, one has cause for concern about the fate of these "failures." The Peace Corps may be viewed as one of the great experiments of this century in the application of humanitarian principles and idealistic efforts to the problems of underdevelopment and international relations with the non-English-speaking world. At a time when the profession of psychology is concerned with the rights of human subjects, it would seem that more than academic concern needs to be expressed for the effect of participating in the "Peace Corps experiment" upon the volunteer subject. This position will receive further discussion later, but first some other observations made by Harris appear to deserve comment from the field point of view.

Evaluation in the Field

The author is in full agreement with Harris's comments on the need for formal evaluation of performance in the field and the implementation of appropriate reward or disciplinary action. A low level of feedback on his performance to the Antarctic volunteer from supervisors in the United States appears to be stressful for these men, and signs of this stress become increasingly evident during

Volunteer (PCV), and while serving as a research assistant in Antarctica. The opinions expressed by the author are personal and are intended only for clarification, and should not be construed as representing, condoning, or criticizing past or present opinion or policy of any agency of the U.S. Government.

The author received Peace Corps training at Hilo, Hawaii, in 1963 and subsequently served a full two years in the field as a community development worker (Thailand VII) during 1964 and 1965. In 1966-1967 he served in the U.S. Antarctic Research Program as a psychophysiological technician and spent a year at the Amundsen-Scott South Pole Station, Antarctica. Since 1967 he has been continuously a research assistant and associate and graduate student at the University of Oklahoma Health Sciences Center. Currently he is a doctoral candidate in biological psychology, Department of Psychiatry and Behavioral Sciences, University of Oklahoma Health Sciences Center, and research associate in the Behavioral Sciences Laboratories of the senior medical investigator (psychiatry), Oklahoma City Veterans Administration Hospital. The author may be contacted at the Hospital, BSL (151A), 921 Northeast Thirteenth Street, Oklahoma City, Oklahoma 73104.

periods when communication with the United States is not possible (Natani, 1971). Law (1960, 1963) made similar observations for Australian personnel. However, Harris suggested that field evaluation has been chronically absent in the Peace Corps organization. This view is at variance with the author's experience during his period of service.

Some formal evaluation of volunteers in Thailand was evident by Peace Corps staff, and this was implemented by visiting individual volunteers, by calling groups of volunteers in for formal meetings, and by holding discussions with individuals while visiting in Bangkok. Rewards were informally distributed to deserving individuals in the form of assistance on special projects, occasionally by supplying motorized transport, and by distributing results derived from their efforts to other volunteers, for example, the books of Kahn (1965), Madden (1965), and Natani (1965a). Also, productive volunteers were chosen for staff positions after completing their assignments. In general, volunteers were quite competitive and diligent in continually seeking ways to improve their performance. On the other hand, the presence of nonproductive individuals disturbed the dedicated who did not agree with the informal policy that attrition was undesirable and that these individuals should not be unduly pressured because this might precipitate their early termination.

A formal system of staff evaluation also appeared to be in operation, and evaluators were encountered periodically in Bangkok. Both the staff and the evaluators encouraged feedback and were open to suggestions. A copy of a report on development activities (Natani, 1965b) was transmitted to Washington, D.C., via an evaluator in 1965. In 1966 a formal recommendation was sent to the Peace Corps director (Vaughn). It contained suggestions for the establishment of career counseling and appropriate evaluation and reassessment procedures for

all volunteers requesting (long-term) extensions of service.

The Problem of Attrition

Several points should be added to Harris's analysis of the problem of attrition. Attrition was already a problem correlated with increased in-country training in 1966 (J. T. English, personal communication). The apparent recent trend toward a reduction of early terminations in training and a rise in early field terminations with in-country training may reflect a group effect. It could also reflect a change, if any, in the policy concerning the undesirability of early field terminations. For in-country training, economic and other considerations involved in returning an individual to the United States now appear to be essentially the same for dropouts whether they occur during training or after assignment. The population of applicants may also have changed, and current trainees may have a different motivational reservoir for social action (Bernard, 1968). In short, the stress-seeking pioneers of the late 1960s and early 1970s may be applying their efforts to other areas. (Incidentally, stress-seeking behavior is another neglected area of research.)

However, a hypothesized group effect may be a more potent factor influencing attrition in the Peace Corps setting. Under the former board system, the selection process appeared to foster interpersonal distance among the trainees, especially when they were involved in the assessment of fellow trainees by the use of peer ratings. In other settings, such as the Antarctic, peer ratings can have undesirable effects (Nardini, Hermann, & Rasmussen, 1962), but they may also be useful in promoting the introspection necessary for valid self-selection during Peace Corps training. With regard to Harris's comment on the conflict between the morale problems of peer rating and humanitarian values, the author feels very strongly that one must consider the stresses to which

the volunteer may be subjected in the field. In making this consideration, the most humanitarian alternative seems to be the application of procedures that will promote attrition in training of those individuals who do not have firm self-identities and high levels of self-esteem. It would seem that only a tough-minded selection process, based on research as Harris (1973) suggested, will lead to his stated goal,

to produce in even larger numbers men and women who are sufficiently realistic in their self-perceptions to be capable of deciding voluntarily what commitments they can fulfill and, having once decided, to be capable of fulfilling those commitments through service to their country and to their fellow man [p. 247].

Positive group interactions and high levels of morale during in-country training may also foster a false sense of competence and accomplishment in the trainees. When the new volunteer arrives in a foreign capital after three months of training in the United States and discovers that he still has language difficulties, he realizes that the training process, at best, cannot provide him with total competence for his new role. The usual response is to make an appropriate adjustment and try to do the best he can with his limited resources. On the other hand, when the in-country trainee discovers that he has problems with the local dialect of his assignment and is finally alone, dependent on his own resources, he may react with frustration, discouragement, and disillusionment regarding his training. Thus, attrition would tend to increase with in-country training. If training stress has been minimized, as Harris indicated, then such a group effect would be accentuated when the trainee finally has to depend on his own resources. In any event, we are certainly in agreement with Harris's comments on the possible negative effects of making training more comfortable. The stressful stateside training for selection purposes, combined with in-country training for job competency which

was supported by Natani in 1966, appears to offer the best alternative.

Performance and Adaptation in the Field

Peace Corps service represents only one instance of a situation in which individuals are separated from their accustomed surroundings. Other examples include new students in college dormitories, missionaries assigned to remote regions, and recruits in military service. The "input" from these new environments and the effects of the social processes operating under such circumstances, however, are often too varied to conduct research studies of the separate factors affecting the individual. For this reason, in our work, we have focused on the Antarctic station as a natural field laboratory for the study of human adaptation to geographic isolation and psychological as well as physical stresses. The complexity of the interaction between these variables is greatly diminished at the isolated station, hence their boundaries may be better defined for research purposes. These studies have dealt with both physiological and psychological variables (Blackburn, Shurley, & Natani, in press; Natani, Shurley, & Joern, in press; Natani, Shurley, Pierce, & Brooks, 1970; Shurley, 1971; and Shurley, Pierce, Natani, & Brooks, 1970).

Investigation of human performance in, and adaptation to, remote and exotic environments is needed, and this position appears to be well-defended by Harris. Nevertheless, if we are to succeed in answering the question posed by him, "what type of individual should be placed in a particular environment . . . [p. 234]?" we need to know more about the influence of our daily transactions in human society at home. Negative reactions to an environment are relatively easy to identify, but the presence or absence of positive responses often depends on the final decision of success or failure for evaluation. The understanding of psychological well-being is another

neglected area of research. If we knew how an individual achieved positive satisfactions from his accustomed environment, we would be in a better position to predict his response to the presence or absence of these opportunities for obtaining a feeling of well-being in another environment. This appears to be essentially virgin territory, but Bradburn and Caplovitz (1965) and Bradburn (1969) have initiated an attempt to determine the effects of differing degrees of environmental stress upon what has variously been called mental health, subjective adjustment, happiness, or psychological well-being. We have also attempted to use a version of their technique, in a pilot study, to assess the positive aspects of Antarctic wintering reported previously by Mullin (1960). Insufficient data are available at this time to warrant further comment, however.

The Psychologist's Role

A volunteer assigned to a remote location in an underdeveloped country may be potentially in a position for exposure to more disease, accidental injury, and psychological trauma than any other representative of his country, including military personnel, if we discount combat situations. It is not surprising that psychological casualties occur. Therefore, it would appear that the primary role of a psychologist or psychiatrist in a volunteer organization should be a responsibility for the mental health of the volunteers. Harris has focused on the role of the psychologist in selection and his recent elimination from the assessment process, but he leaves the reader in suspense regarding the fate of the Peace Corps psychologist's presence for the prophylactic and therapeutic service. At the very least it seems that the reduction of the psychologist's intimate association with volunteers during training would make his performance as a clinician more difficult when called upon to attend to problems arising in the field. English and Coleman (1966) described

four major periods of psychological difficulty during overseas service that is, (a) the crisis of arrival, (b) the crisis of engagement, (c) the crisis of acceptance, and (d) the crisis of reentry. Similar phases of adjustment may be seen in Antarctic volunteers. These crises of adjustment may not be severe, but some individuals may need support during these phases, and especially during the reentry crisis. If recent administrative policies have weakened or curtailed the mental health support system established in the past to deal with the problems of the returning volunteer, then there is justified concern within the profession of psychology (and elsewhere) for the possible negative consequences of this policy.

Attitudes of Psychology Students Toward Drug Abuse

Stachnik (1972) proposed to do away with criminal penalties for illicit drug use and to offer heroin at methadone clinics for recalcitrant drug users. By contrast, Pratt (1972) summarized a report urging indeterminate periods of civil commitment in compulsory work camps for heroin abusers, with methadone and psychotherapy followed by parole. In a survey of 174 Veterans Administration trainees' attitudes toward drug abuse, an antipathy for use of the prison system was evident. Preferred treatment modalities for opiate abusers were: therapeutic community (63.2%), synthetic narcotic as methadone (62.1%), group psychotherapy (58.0%), and halfway house (56.3%). Court probation, jail term, and tranquilizing medication each received support from less than 5% of the group. When the respondent was asked to check the circumstances under which the prison system was to be preferred to the hospital system, one third of the group selected under no

circumstances. A larger number (55.2%) selected the prison system for use plus criminal activity, but the category use plus "pushing" (27.6%) received less support than under no circumstances. Even those unmotivated for treatment were rarely considered candidates for prison. Homogeneous hospital patient groups were preferred, and special hospitals were frequently endorsed for alcohol and heroin abusers. The high regard for freedom of movement was also reflected in endorsements of outpatient treatment and open ward care.

Trainees felt the use of methadone was ethical (80.5%), and the treatment was successful if a hard narcotic user switched to a milder drug such as marijuana (77.6%). About half of the group felt a drug abuser would tell of his drug use, but more than half felt drug abusers would not acknowledge a personal need for treatment (63.8%) or seek recommended treatment (76.4%). Acknowledging the importance of high motivation for hospital care to achieve treatment success (94.3%), prognosis was considered poor (77.0%); users were considered likely to decrease abuse temporarily (87.4%), but unlikely to stop (73.6%).

Trainees' personal experience working with drug abusers was limited, usually less than a quarter of their professional time (47.1%) or none (42.5%). They had relatively limited knowledge about hospital facilities for reality testing an abuser's verbal statements about current drug use. Many of them (44.3%) were willing to undertake full-time work with drug abusers, and 23.6% were unwilling. Stated differently, 53.4% were willing to devote 50%-100% of their professional time to treating drug abusers, and 43.1% were willing to devote quarter time or none. Trainees were more willing to treat drug abusers than alcoholics; only a third of them would spend half-time or more with the latter.

The discrepancy between the trainees' support of treating drug abusers in an open setting and their general

pessimism about the effectiveness of treatment is apparent. Nevertheless, many of them are willing to treat drug abusers and necessarily need the educational background to do so. Coping with the problems of drug abuse should certainly be included in graduate school curricula and practicum experience. Opportunities for such training may develop rapidly within law enforcement agencies (Reiser, 1973). The prejudice exhibited toward the legal system may be unrealistic in the *Zeitgeist* that produces much stricter drug penalties in New York State (Newsweek, 1973). The penchant for personal freedom may offer a method of conceptualizing the negative aspects of heroin addiction in preventive education for young target groups. Heroin addiction may legitimately be viewed as limiting choices and personal freedom.

Time for Cerberus to Give His Name

It is the nearly universal practice among editors of scientific journals to transmit submitted manuscripts to one or more referees for evaluation. Some journals attempt to keep the authors anonymous, with respect to the referees, although this practice is often not feasible. In nearly all cases, however, the tradition is observed that the referees remain anonymous, both to the authors whose work may be rejected (sometimes mistakenly or carelessly) and to the

readers of the articles that have been accepted (also sometimes inappropriately).

This tradition of anonymity seems out of keeping with the present spirit of accountability and openness in other areas of society. If I accept the responsibility to recommend (and thus usually to determine) that a paper ought to be rejected, if I compose a list of criticisms, often embellished with derogatory adjectives, should not the author who has invested deeply of his ego and efforts in the manuscript be at least entitled to know who I am? More importantly, if I know that I shall have to sign my critique, will I not therefore be inclined to do a better job of refereeing? Similarly, if I understand that my name will be printed in a footnote to each article whose publication I have recommended, am I not then less likely to approve a complex paper without really understanding it or a trivial paper whose rejection, while appropriate, might be taxing to explain?

Refereeing manuscripts is an onerous and thankless task; one hesitates to make it any more demanding. But, as an experiment, for the past year I have been signing my own critical reviews; it really isn't that difficult. I believe that it does make me try to be surer of the grounds on which I criticize, and I know that I'm less liberal with gratuitous insults than I tended to be when I was still cloaked in lordly anonymity. Moreover, I do not believe that one necessarily becomes less critical in a signed review or more likely to recommend acceptance of a borderline product. And I am certain that one would not recommend acceptance lightly if one's name were to be printed with the paper in question.

The referee has a responsibility both to the authors and to the readers of scientific papers; he should be accountable to both constituencies also. It is time, I submit, for Cerberus to start giving his name.

Announcements

Changes in Experimental and Comparative-Physiological Journals. Scheduled for 1975

The APA Publications and Communications Board has announced changes in the *Journal of Experimental Psychology (JEP)* and the *Journal of Comparative and Physiological Psychology (JCPP)* to take place in 1975. The changes reflect the outcomes of surveys of member subscribers to those journals conducted in May 1973. The major effect is in *JEP*, which will be published in four sections. Some material previously appearing in *JCPP* will now be published in the reformatted *JEP*.

The new policies have the support of outgoing editors David A. Grant, of *JEP*, and Eliot Stellar, of *JCPP*, as well as *JCPP* editor-elect, who will be Garth J. Thomas, University of Rochester, and the four editors-elect of the independently distributed sections of *JEP*, who will be Gregory A. Kimble (*General* section), University of Colorado; Lyle E. Bourne (*Learning and Memory*), University of Colorado; Michael I. Posner (*Perception and Performance*), University of Oregon (currently Visiting Professor at Yale University); and Allan R. Wagner (*Animal Behavior Processes*), Yale University.

These changes are of immediate importance to contributors to *JCPP* and *JEP* because the publication lag in both journals now approximates 12 months. Manuscripts should be submitted to the new editors after January 1, 1974 (for *JCPP*) or after March 1, 1974 (for sections of *JEP*) (see addresses below).

The P&C Board's action on *JCPP* removes animal experimental studies of perception, learning, motivation, and performance in which the central thrust is toward general behavior theory. These reports will be accommodated in *JEP* in either the *General* section or the section on *Animal Behavior Processes*. The *JCPP* will

continue to publish research reports chiefly directed toward elucidation of physiological, anatomical, or chemical mechanisms of behavior or toward elucidation of biological (including genetic), species-specific mechanisms of behavior. Refinement of these guidelines will be monitored continuously by the editors of *JCPP* and *JEP*.

The Board's action on *JEP* in 1975 is to publish it in four independently edited and distributed sections to which members may subscribe singly or in self-selected combinations. The *Journal of Experimental Psychology: General* (Gregory A. Kimble, Editor) will publish articles in any area of experimental psychology when they are judged to present an integrative report of new research leading to a substantial advance in knowledge. It will include, but not be limited to, articles such as have appeared as *JEP Monographs* and as chapters in contemporary books of "advances" in which authors present the theoretical-empirical implications of their own research programs in a comprehensive fashion intelligible to the general experimental psychologist.

The *JEP: Learning and Memory* (Lyle E. Bourne, Editor) will publish experimental studies on fundamental learning and memory processes in human behavior. An illustrative, but not exhaustive, list of appropriate topics is human conditioning; motor learning; complex discrimination learning; sequential response and probability learning; verbal learning, transfer, and retention; encoding strategies, insofar as they are related to memory; learning to learn; concept formation and abstraction processes; problem solving; deductive reasoning.

The *JEP: Perception and Performance* (Michael I. Posner, Editor) will

publish studies designed to foster understanding of information-processing operations and their relation to experience and performance. An illustrative, but not exhaustive, list of appropriate topics is sensory transduction, pattern recognition, perception, attention, motivation, thinking, decision making, stress, and motor control. Dependent variables may be response speed or accuracy, thresholds, verbal protocols, autonomic or CNS activity, or other measures. Studies of perception and performance are often closely linked to physiology and to engineering applications, and contributions with these emphases are also encouraged.

The *JEP: Animal Behavior Processes* (Allan R. Wagner, Editor) will publish experimental studies of basic mechanisms of perception, learning, motivation, and performance with infrahuman animals, in which the principal focus is on concepts and issues in general behavior theory. It will, therefore, reinstate animal experimental studies as a major component of *JEP*, rather than having them split between *JEP* and *JCPP* as minor components of each of those journals.

The above statements reflect the thinking of the APA Publications and Communications Board, but more particularly the thinking of the newly appointed editors of *JEP* and *JCPP*. Further refinements and expansions of these statements will appear in early 1974 issues of the journals. In the case of *JEP*, the four editors of the sections will also serve as members of a Board of Editors of *JEP* and will collaborate continuously in establishing standards of acceptance, allocation of articles to sections, and page allocations. The page allocation to *JEP* in 1975 has been established by the Publications and Communications Board at 2,400 pages, with tentative allocations to sections of 400 for *General*, 800 for *Learning and Memory*, 400 for *Per-*

ception and Performance, 400 to *Animal Behavior Processes*, and 400 in a "page bank" from which pages will be released to sections, if needed, on the basis of consultation between the Board of Editors of *JEP* and the Chair, Publications and Communications Board. In the case of the *JCPP*, the page allocation for 1975 is 1,200, with an additional 300 pages in a "page bank" from which pages will be released by joint agreement between the Editor, *JCPP*, and the Chair, Publications and Communications Board, in the interests of reduction in publication lag. It is the expectation of the Publications and Communications Board that the Editors of the *JCPP* and the sections of *JEP* will be sufficiently selective to maintain a publication lag of not greater than 12 months, while remaining within their overall page allocations.

The addresses of the editors-elect of the two journals are: *JCPP*: Garth J. Thomas, Center for Brain Research, University of Rochester Medical Center, Rochester, New York 14642; *JEP: General*: Gregory A. Kimble, Department of Psychology, University of Colorado, Boulder, Colorado 80302; *JEP: Learning and Memory*: Lyle E. Bourne, same address as Kimble; *JEP: Perception and Performance*: Michael I. Posner, until June, Department of Psychology, Yale University, 333 Cedar Street, New Haven, Connecticut 06520; after June, Department of Psychology, University of Oregon, Eugene, Oregon 97403; *JEP: Animal Behavior Processes*: Allan R. Wagner, Department of Psychology, Yale University, 333 Cedar Street, New Haven, Connecticut 06520.

Predoctoral, Doctoral, and Postdoctoral Programs

Adelphi University Postdoctoral Program in Psychotherapy: Now accepting applications for admission for fall semester 1974. The Program in the Institute of Advanced Psychological Studies is a four-year curriculum in psychoanalysis and psychotherapy encompassing personal therapy, supervision, academic courses, seminars, and research. The Program is also accepting applications for its two-year specialty program in group psychotherapy for fall semester September 1974. A PhD in psychology and two years of postdoctoral psychotherapy training are requisites for admission. For further information and applications for either program write to Donald S. Milman, Codirector, Postdoctoral Program in Psychotherapy, Institute of Advanced Psychological Studies, Adelphi University, Garden City, New York 11530. When requesting information, specify which program.

Columbia University Graduate School of Arts and Sciences: Now accepting applications in cooperation with the School of Public Health of the Faculty of Medicine for a PhD program in epidemiology for the fall semester 1974. Students enrolled in the program will have an opportunity to address major health problems of society from an interdisciplinary research perspective. The program permits specialization according to the student's background and in-

terests in biomedical, social, or statistical epidemiology. Areas of study include the measurement of manifestations of disease and related social and behavioral phenomena, the design of field surveys, procedures for collecting and handling large bodies of data, and statistical analyses. Majors in the social sciences, biological sciences, or in mathematics and statistics with supporting background in either of the two other fields are considered to have good preparation for this doctoral program. Graduates with excellent backgrounds and achievements in other disciplines will also be considered. For further information write to Robert Friis, Division of Epidemiology, Columbia University School of Public Health, 600 West 168th Street, New York, New York 10032.

Los Angeles County—University of Southern California Medical Center: Now accepting applications for postdoctoral fellowships in child-adolescent clinical psychology. The program includes training and supervision in crisis intervention therapy (inpatient and outpatient), behavior modification, and community mental health with children, adolescents, and parents. Other special interest areas available are pediatric psychology, delinquency, suicide prevention, drug abuse, abortion counseling, free clinics, etc. Prerequisites: a doctorate (PhD or EdD) from an accredited graduate program in psychology and one-year internship or equivalent. Stipend \$8,200 for 12 months, period beginning July 1974; applications must be completed by May 15, 1974. For more information write to Ruth Sinay, Director, Child-Adolescent Psychological Training Program, Los Angeles County-USC Medical Center, 1934 Hospital Place, Los Angeles, California 90033.

Postgraduate Center for Mental Health: Now accepting applications for comprehensive professional training in psychotherapy and psychoanal-

ysis for 1974-1975. The program offers opportunities to acquire knowledge and experience in child, adult, group, and family therapy as well as community mental health education and research. While doing therapy with a broad spectrum of patients, the candidates will be instructed by highly skilled supervisors formerly trained at the Center. Applicants must have a doctoral degree in psychology. Part-time and full-time appointments available. Stipends of \$6,000 the first and \$7,000 the second year available for full-time candidates. Training leads to certification in psychotherapy and psychoanalysis. For further information write to Benjamin Fielding, Dean of Fellowship Training, 124 East 28th Street, New York, New York 10016.

Community Psychiatry Section, Department of Psychiatry, University of North Carolina School of Medicine: Now accepting applications for advanced study in the leadership and administration of community mental health programs and centers. Tutorial, didactic, and practicum teaching provided by experienced faculty of psychiatrists, psychologists, epidemiologists, biostatisticians, public health administrators, social workers, psychiatric nurses, and social scientists. Emphasis: leadership and administration, analysis and evaluation of mental health programs, research and theoretical foundations of mental health programs. Completion of 12-months' training provides eligibility for mental health program administration certificate, completion of 21-months' training with major in School of Public Health provides eligibility for master's degree. NIMH postdoctoral stipends for psychologists: \$6,500 (\$3,600 tax exempt), including tuition and fees, travel during training and dependency allotments are provided. Additional supplement for training-related field experience (minimum \$2,000). Available for fall 1974 and future years. *Applications for 1974-1975 program should be submitted before April 1, 1974.* For

further information write to William G. Hollister, UNC School of Medicine, Drawer 801, Chapel Hill, North Carolina 27514.

Massachusetts College of Optometry: Now accepting applications for a new professional program: Doctor of Optometry (OD). The purpose of this program is to provide the PhD in the physiological, behavioral, physical, or applied sciences with an opportunity for accelerated study toward the OD degree. Health professions scholarships and loans are available in limited amounts. These funds may only be awarded to U.S. citizens or those foreign-born candidates who have achieved permanent resident status. For further information write to Joseph Jefferson, Division of Special Studies, Massachusetts College of Optometry, 424 Beacon Street, Boston, Massachusetts 02115.

Award

Twelfth Annual Creative Talent Awards Program 1972-1973, American Institutes for Research: Winner of First Award of \$2,000, Alison Clarke-Stewart, Yale University, for dissertation entered in the Human Developmental Psychology field, entitled "Interactions between Mothers and Their Young Children: Characteristics and Consequences." Best-in-Field winners: Robert T. Hennessy, Pennsylvania State University, in the area of Psychophysiology, \$1,000 award for work entitled "Stimulus and Nonstimulus Factors Affecting Accommodation with Particular Reference to Instrument Myopia"; Patricia A. Carpenter, Stanford University, in the area of Learning and Motivation, \$1,000 award for work entitled "Referential Meaning in Sentence Comprehension and Memory." Seven honorable mentions: Ronald R. Rossi, University of Cincinnati; Ovid Jyh-Lang Tzeng, Pennsylvania State University, in the Sensation and Perception, Learning

and Motivation, Psychophysiology, and Comparative Psychology field; Mark Snyder, Stanford University; Larry L. Venham, Ohio State University; Marsha C. Winokur, Yeshiva University, in the Human Developmental Psychology, Personality and Mental Health, and Social Processes area; Carolyn L. Cason, University of Texas; Morris Kwong-You Lai, University of California at Berkeley, in the Measurement and Evaluation, Educational Psychology, and Problem Solving, Decision Making, and Psycholinguistics category.

American Board of Professional Psychology

The American Board of Professional Psychology is pleased to announce and thank the following diplomates who served as oral examiners or field observers of 1972-1973 candidates for ABPP Diplomas in Clinical, Counseling, Industrial and Organizational, and School Psychology:

Personal Relationships and Personal Constructs: A Study of Friendship Formation

By S. W. Duck, *University of Lancaster, England*

What are the causes of attraction: of friendship, of love, or of marital choices? Why do we get on better with some people than with others? Such questions have everyday importance when we spend so much of our time dealing with and meeting other people in a society. This book charts the progress of an investigation into the processes of friendship formation, attacking the question on both a theoretical and empirical front.

The Origins Of Behavior:

The Effect of the Infant on its Caregiver, Vol. I

Edited by Michael Lewis, *Educational Testing Service*, and Leonard A. Rosenblum, *State University of New York, Downstate Medical Center*

This volume centers on the effect that the infant may have on its caregiver, particularly focusing on the infant as a source of the formation, regulation, and even the malevolent distortion of the caregiver's behavior. It studies the effect of infant defects on caregivers from a variety of viewpoints, using both humans and monkeys as subjects, while also examining in normal infants, data drawn from many levels of discourse including morphology, physiology, and behavior.

Simulation in Human Systems: Decision-Making in Psychotherapy

By Richard Bellman and Charlene Paule Smith, *both of the University of Southern California, Los Angeles*

This book fulfills three major objectives: (1) to illustrate certain contemporary mathematical concepts and methods applied to decision processes occurring in a human interaction system, (2) to provide an introduction to the powerful and versatile technique of simulation, and (3) to describe how computers may be used to increase the effectiveness of simulation processes used in research and teaching.

New Approaches in Psychological Measurement

Edited by Paul Kline, *University of Exeter*

Experts in each of the respective fields describe the latest techniques and developments in psychological measurement. Dealing with the major areas of theory technique and application, the book covers the statistical bases of psychological testing, intelligence and personality testing, projective tests and the Rorschach, assessment in psychodynamic psychology and physiology, and the problems of psychological testing.

and topics of current interest.

Brain Control: A Critical Examination of Brain Stimulation and Psychosurgery

By Elliot S. Valenstein, *University of Michigan*

Brain Control traces the fascinating story of man's attempt to control his own brain. The range of topics is wide, including the modification of behavior and emotions in animals and man by electrical and chemical brain stimulation, psychosurgery, electroconvulsive shock treatment, prosthetic devices for the blind and deaf, biological approaches to controlling aggression in children and adults, controlling pain, and many others.

Identity and Community in the Gay World

By Carol A. B. Warren, *University of Southern California, Los Angeles*

This book takes a close look at the ways in which members of a secret gay community relate to each other and to the "straight" world that regards them as deviants. Rich in ethnographic data and direct quotations, it examines the problems of identity they encounter, as well as the conflicts and tensions that are produced within the gay community by their social and psychological ambiguities.

After Suicide

By Samuel E. Wallace, *New York University*
Foreword by Theodore Caplow

How did 12 women survive their husbands' suicides? Studying the experience of widows faced with the loss of a loved one, Dr. Wallace traces, through in-depth interviews, each woman's path to survival, and explores the larger question of how people confront, experience, and survive this life-threatening crisis.

Ego Functions in Schizophrenics, Neurotics, and Normals

A Systematic Study of Conceptual, Diagnostic, and Therapeutic Aspects

By Leopold Bellak, *New York University*,
Marvin Hurvich, *The Roosevelt Hospital*, and
Helen K. Gediman, *Albert Einstein College of Medicine*
A volume in the *Wiley Series on Personality Processes*,
edited by Irving B. Weiner

This book reports the results of a five-year research study supported by the National Institute of Mental Health, in which a detailed new methodology was developed for assessing psychopathy through an ego function approach derived from clinical research methodology. It presents material for assessment, along with an interview guide, manual, and rating form.

**NEW IN
PAPERBACK
FROM
FAWCETT**

"A TRUE PSYCHOLOGICAL THRILLER."

"A family that seemed to have everything—money, status, talent, education, charm—produced in its third generation three emotionally disturbed children. The sole survivor of the three, a psychologist, recounts the story to Dr. Parker. It is a study of mental illness, informative and engrossing, with all the virtues of a novel—a true psychological thriller." —*New York Magazine*

"What a story! This admirable book, a study of the social genesis of madness, manages to combine the facts of a case-history and the atmosphere of a fairy tale, a *bad* fairy tale of chilling deterioration and disaster." —*New York Times Book Review*

"A chilling, intimate story of the destruction of a family, one that anyone interested in emotional health and family problems will find difficult to put down . . . a genuine psychological drama . . . that will obviously be a gold mine for the professional." —*Publishers Weekly*

THE ESSENTIAL PUBLICATION

dsh ABSTRACTS

VOLUME 202 NUMBER 1 January 1974

Published by DEAFNESS SPEECH AND HEARING PUBLICATIONS, INC.
An organization founded by the AMERICAN SPEECH AND HEARING ASSOCIATION and GALLAUDET COLLEGE

The "ESSENTIAL" publications for specialists concerned with human communications and its disorders.

Designed to keep you abreast in scientific, educational, and clinical developments in the fields of deafness, hearing, speech, and language.

Designed for the clinician—researcher—educator.

BREADTH OF COVERAGE

- Abstracts of current world literature from over 400 scientific, educational, and technical journals.
- Abstracts pertinent to this field from major allied abstracting services—*Excerpta Medica Foundation, Psychological Abstracts, Child Development Abstracts and Bibliography, Rehabilitation Literature, and Education Abstracts.*
- Abstracts from foreign language as well as English publications.

AREAS OF COVERAGE

dsh Abstracts is a quarterly journal established to provide within a single cover comprehensive and current coverage in the areas of:

Speech Pathology / Audiology
Voice Science / Experimental Phonetics
Psychoacoustics / Education of the Deaf

Deafness Speech and Hearing Publications
9030 Old Georgetown Road
Washington, D. C. 20014

Subscription Rates (please check one)

UNDERSTANDING HUMAN BEHAVIOR

by James V. McConnell of the University of Michigan

Comprehensive, dramatic introduction to principles of psychology emphasizing positive, constructive and rewarding approach to learning.

Human behavior analyzed from three points of view: *intrapsychic, biological, and social/behavior.*

Fictionalized case histories, experiments and illustrative stories provide intriguing preview of chapter content. Topics include: Sperry's split-brain work, Rosenhan's work on accurate sanity diagnosis.

Personal and social concerns fully developed in both textual and fictional material. Topics include: biofeedback, Transactional Analysis, human sexuality.

Research experiments presented from point of view of experimenter (why he/she planned it that way) and the subject (how he/she perceived the experiment).

Running glossary contains definitions of psychological terms, more difficult everyday words, related references, author's comments, and chapter summaries.

REVIEWER COMMENTS:

"I was immediately struck by the high readability of the chapters and the fictional vignettes beginning and ending each chapter. There is little doubt that J. V. McC. has apprehended his goal: an introductory psychology text written for all students."
Elliot Entin, Ohio University

"Overall, I would have to say that the work is very thorough, scholarly and well written, giving significant concepts in a generally interesting manner. It should appeal to students at a variety of intellectual levels."
Robert Hoeppner, Orange Coast College

"My general impression is that you've got a winner."
Charles G. Halcomb, Texas Tech University

720 Pages/February 1974/\$10.95 (tentative)

Also Available to Accompany the Text—
STUDENT MANUAL by Lawrence Al Siebert, Oregon State System,
and Timothy Walter, Rhode Island College

Provides a complete review of the textual material, a series of "prescriptions" on how to study and how to pass exams, detailed step-by-step reviews of chapter material, true-false test questions, individual action projects, and readings.
128 Pages/February 1974/\$2.50 (tentative)

INSTRUCTOR'S MANUAL by Lawrence Al Siebert and Timothy Walter.
Includes chapter summaries, content objectives (major learning points), list of films and sources, and suggested class demonstrations.

96 Pages/February 1974

TEST ITEM FILE BOOKLET by Lawrence Al Siebert and Timothy Walter.
Over 900 true/false and multiple choice questions laid out for easy assembly as a card file.

320 Pages/February 1974

RANDOM HOUSE 
THE COLLEGE REVIEW DESK 457 HAHN ROAD, WESTMINSTER, MARYLAND 21157

Alfred A. Knopf is proud to announce
the third edition of

Elements of Psychology

David Krech and **Richard S. Crutchfield**
both of the University of California, Berkeley; and
Norman Livson, California State University, Hayward; with
William A. Wilson, Jr., University of Connecticut, Storrs

What's new and different in the **third edition**? Here are a few of the features which keep this book at the forefront of change in a rapidly growing, widely expanding field:

- a new and extensive unit on **altered states of consciousness**.
- a significantly expanded consideration of **psychological disorders** and the **psychotherapies** which have been developed to cope with them.
- a fresh and broader look at the field of **social psychology**, including a completely **new unit** on Morality, Aggression, and Equity.
- a restated treatment of **developmental linguistics**, reflecting the intellectual ferment within this very "hot" area of research.
- an interweaving of **developmental** and **behavior genetics data** throughout the text wherever these areas can contribute to our understanding of psychological phenomena.
- a candid assessment of the data on **"IQ and race"**.
- **AUTHORITATIVE**—in addition to incorporating the most recent research in the third edition, the authors sought out experts in particular fields to contribute additional expertise, e.g. Dan Slobin on language, Michael Lerner on heredity and behavioral genetics, Marjorie Honzik on intelligence, Charles Tart on altered states of consciousness, and John M. Kennedy on perception.

March, 1974 750 pages \$11.95 Order Code 31768

Focusing on Psychology:

A VISUAL APPROACH

SLIDE GROUP FOR GENERAL PSYCHOLOGY: SET 2, Dr. James B. Maas

150 35mm color slides for use in addition to or independently of the original slide group now being used in over 1200 colleges and universities. Set 2 is divided into six major categories of central concern to the field of psychology:

1. PSYCHOPHYSIOLOGY OF SLEEP AND DREAMING
2. INSTRUMENTATION FOR RESEARCH AND DEMONSTRATION OF PSYCHOLOGICAL PHENOMENA
3. LEARNING CONCEPTS AND EXPERIMENTAL PARADIGMS
4. ASSESSMENT CONCEPTS AND TECHNIQUES
5. PAINTINGS BY THE DISTURBED MIND
6. THE EMOTIONAL BRAIN AND NEUROPSYCHIATRIC THERAPIES

An excellent supplement to lectures or as core material for building modules, mini-courses, and related audio-tutorial, self-study programs. Requires only a standard 35mm slide projector and screen.

1974, \$150.00 net; Instructor's Manual

SLIDE GROUP FOR GENERAL PSYCHOLOGY Dr. James B. Maas

Comprehensive group of 300 35mm color slides to amplify, illustrate, and demonstrate both introductory and advanced psychology materials.

1967, \$300.00 net; Instructor's Manual; Study Guide

MULTI-MEDIA PSYCHOLOGY INSTRUCTIONAL KITS, Wendell I. Smith

Three individual units designed for lecture hall use. To help instructors achieve coverage of the basic material in psychology.

1. **Statistical Decisions:** 8 overhead transparencies with 28 overlays. Logical, non-mathematical presentation in which statistical reasoning is taught.
\$100.00 net; Instructor's Manual
2. **Human Learning:** 21 35mm cardboard-mounted slides and 5 overhead transparencies with 11 overlays. Summarizes traditional concepts and categories of learning.
\$85.00 net; Instructor's Manual
3. **Psychophysics:** 80 minute audio-tape on a 7-inch reel. 6 overhead transparencies with 12 overlays. Covers psychophysics using an inductive method.

PLACEMENT SERVICE—EASTERN PSYCHOLOGICAL ASSOCIATION

1974 MEETING APRIL 18-20

PHILADELPHIA

A Placement Service again will be offered at the annual meeting of the Eastern Psychological Association, to be held April 18-20 at the Sheraton Hotel in Philadelphia, Pa. The PLACEMENT CENTER will be open in the hotel on Thursday and Friday, April 18-19 between 10:00 a.m. and 5:00 p.m. and on Saturday, April 20 from 9:30 a.m. to 2:30 p.m.

Preregistration of applicants is vital. The DEADLINE for preregistration is March 30, 1974.

Since 1970, the EPA has managed the Placement Service entirely by volunteers. The cooperation—and patience—of applicants and employers will be essential for the effective operation of the service. Preregistration of both applicants and employers is strongly urged in order to avoid unnecessary delay and confusion during the convention. A booklet will be prepared including preregistered positions only.

Employers who use the placement facilities will be charged \$15 for *each* job description listed. Applicants will be charged \$3.

The preregistration coupon below, *accompanied by the appropriate fee(s)*, should be sent to either Cochairman for the Placement Service:

Dr. Joseph DuCette

or

Dr. Emil Soucar

PSYCHOLOGY OF PERSONALITY, Fourth Edition, Ross Stagner

A general introduction to the psychology of personality. Reflects the burst of research information since 1960 in the areas of brain function, biochemistry, and psychophysiology. More emphasis is on biological aspects of personality without reversing previous edition's emphasis on social molding. Includes more physiological and neurological material, more intensive integration of cognitive research in the treatment of personality, more comments on the comparative treatment of given phenomena by different theoretical schools of psychology. Provides an introduction to all varieties of research on the normal adult personality. 1974, 640 pages, \$10.95.

PERSONALITY DEVELOPMENT, Elizabeth B. Hurlock

A comprehensive, practical introduction to personality based on factual information from extensive research studies. Concentrates on three major areas: (1) The Meaning of Personality, (2) Personality Determinants, (3) Evaluation of Personality. Attempts to substantiate or disprove well-known theories and traditional beliefs about personality. Elaborates on the Freudian concept of symbols of self. Offers a practical approach to an understanding of different levels of adjustment in sick and healthy personalities. 1974, 520 pages, \$10.95.

PERSONALITY DEVELOPMENT, Second Edition, Henry Clay Smith

Relevant to the student's desire to understand himself, this introductory text stresses personality and interpersonal relationships. Personality is approached from four related but distinctive points of view: The Science of Personality, Traits as Personality, The Self as Personality, and Roles as Personality. Three carefully selected and interlocking theories are employed so as not to overwhelm the student with a multiplicity of theories or limit his understanding to one approach. 1974, 576 pages, \$10.95.

Prices subject to change.

READINGS IN PERSONALITY

Edited by Harriet N. Mischel and Walter Mischel, *both of Stanford University*

This collection of articles presents major theories, issues, and research in personality. While the selections parallel the organization of Mischel: *INTRODUCTION TO PERSONALITY*, this book has been designed to serve as a complete independent volume. Extensive introductory material is provided to aid the reader in understanding the concepts presented by the individual articles. Selections in Part I offer samples of some of the major theoretical orientations to personality and their associated assessment techniques and applications. Part II covers personality development and basic processes.

1973/494 pages/\$8.95 paper

INTRODUCTION TO PERSONALITY

Walter Mischel, *Stanford University*

"Viewed strictly as a teachable undergraduate text, Mischel's new volume seems better organized, more clearly presented, and the most effective new work. While it carries a social learning, behaviorist orientation, it presents the major issues in the field in a succinct and remarkably pointed fashion so that the more humanistically oriented instructor can use the book to good advantage." Jerome L. Singer, *Yale University*, from the 1972 *ANNUAL REVIEW OF PSYCHOLOGY*.

Instructor's/Test Manual

1971/544 pages/\$11.00

MAINSTREAM PSYCHOLOGY: A Critique

Benjamin M. Braginsky, *Wesleyan University*, and Dorothea D. Braginsky, *Fairfield University*

MAINSTREAM PSYCHOLOGY reviews and analyzes the role of psychology as a profession and as a social force. Avoiding technical jargon, the book includes an analysis and critique of the methodology, theories and practices of psychology with particular focus on behaviorism and humanism. The book provides a social psychological model for understanding and evolution and development of the field, and integrates disparate criticisms of psychology and other social sciences into one comprehensive framework.

March 1974/192 pages/\$4.50 paper; \$7.95 hard cover (tent.)

BEHAVIORAL SELF-CONTROL

Carl Thoresen, *Stanford University, School of Education*, and Michael J. Mahoney, *Pennsylvania State University*

As man becomes more concerned about the advances of systematized behavior control, the importance of personal freedom and humanistic choice become more apparent. *BEHAVIORAL SELF-CONTROL* points out that the technology of behavior change can be meaningfully and productively self-applied toward personalized goals. Blending humanistic concerns and behavioral means, this interdisciplinary book offers a comprehensive data-oriented review and evaluation of existing theory and research on self-control.

FIVE SIGNIFICANT TITLES from BOBBS-MERRILL

A classical approach—updated
B. R. Bugelski's

An Introduction to the Principles of Psychology

Second Edition

630 pages

Cloth ISBN: 0-672-51809-0

Paper ISBN: 0-672-81268-6

\$11.00

\$ 5.95

In preparing the first edition of his book, Professor Bugelski applied modern psychological research to the basic problem of psychology unchanged since Plato's day: that of thinking, feeling, and willing or motivation.

In this revised edition, Bugelski brings the reader up to date on experimental findings, and also takes into account a great many areas—attention, memory, imagery—that allow him to elaborate a genuine cognitive psychology.

Four entirely new chapters—three on learning and a fourth on concept formation—have been added. The others have been completely revised. Instructor's Manual Available. Student Workbook in Preparation.

Visual and Auditory Perception

by Gerald M. Murch

416 pages

\$9.00

Paper ISBN: 0-672-80779-4

The most thorough and up-to-date text available, this book covers the entire field, interrelating the classical, phenomenological approaches of the earlier perceptual scientists with the empirical approach of the new generation. It concentrates on visual and auditory perception, setting up a model of the perceptual processes which accounts for all varieties of perception. Instructor's Manual Available.

SELECTED PAPERS OF DAVID WESCHLER

by DAVID WESCHLER

with introductory material by
ALLAN J. EDWARDS

Here is a comprehensive, wide ranging compendium of the work of one of the twentieth century's foremost psychologists—David Weschler. Perhaps best known as the author of the WAIS, WISC, and WPPSI, Weschler has made important contributions to many areas of theoretical and clinical psychology. This book reflects that breadth, ranging as it does from his earliest work in experimental psychology to his later concerns with the very nature of intelligence and its role in the modern world.

Among the original concepts and important problems discussed in the book are:

- Non-intellective factors in intelligence
- Global intelligence
- The use of deviation IQ at all age levels
- The difference between machine and human intelligence
- The range of human capacities
- The role of intelligence in the modern world

This book will be both fascinating and valuable to all clinical, school, and counselling psychologists, personality psychologists, and users of the Weschler Scales of Intelligence.

1974, in preparation

new DORSEY

STUDIES IN PERSONNEL AND INDUSTRIAL PSYCHOLOGY, *Third Edition*

Edited by EDWIN A. FLEISHMAN, *American Institutes for Research*, and ALAN R. BASS, *Wayne State University*

This book is designed for use in personnel, industrial, and organizational psychology. It is particularly appropriate for introductory and survey courses in these fields. The content in this new Third Edition has been condensed. About 45 percent of the articles are new and of these most have appeared since 1967.

As in the previous two editions, this Third Edition retains a balanced coverage of the field of industrial psychology, while stressing more recent and socially relevant issues of concern to the field. Examples of topics covered which are new include assessment centers, training of hard-core unemployed, discrimination in employment testing, organizational development, and the four-day work week.

PSYCHOLOGY IN INDUSTRIAL ORGANIZATIONS, *Third Edition*

LAURENCE SIEGEL and IRVING M. LANE,
both of Louisiana State University

Intended for undergraduate students enrolled in survey courses variously designated Business Psychology, Industrial Psychology, or Industrial and Organizational Psychology. Through deletions and additions, the authors have integrated recent research literature into their discussions of "traditional" topics carried over from previous editions. This has led to expanded coverage of such topics as testing and training for disadvantaged employees, job enlargement, laboratory training, etc. The balance of the text has been altered by reducing the proportional coverage of topics in personnel psychology and increasing proportional coverage of topics in human relations and organizational psychology.

"... a book every professional should read. Not to read it—is dangerous."

SURVIVAL: BLACK/WHITE

Florence Halpern *Pergamon General Psychology Series, Volume 15*

"Florence Halpern has written a book the whole world should read—at least every American, and certainly every student of psychology, education, psychiatry, and social work. This book should be placed on every college reading list in the social sciences.

In her preface, Dr. Halpern states:

This book is about black people. Since I am white I think some explanation for what may be regarded as presumptuous behavior on my part is indicated. My purpose is to communicate to others how I became involved in the lives of the southern black people and how my perception and understanding of them changed as the result of that involvement. My hope is that what is written here will help other white people 'feel and think black.'

She succeeded with me, and while I myself work with predominantly black people and I have developed perceptions and understandings of my own, Dr. Halpern has helped me immeasurably in increasing my abilities to 'feel and think black.'

Walking in the black man's shoes is essential for those of us who are not black, but who are intimately involved in the struggle the black people are now waging

to assert their economic, political, and psychological rights. . . .

Dr. Halpern is a gifted psychologist. She has made many contributions not only to the clinical understanding of people, but to the field of psychology itself. She has helped it grow as a profession. Now she alerts that profession to the dangers of putting stamps of psychological approval on researches, poorly conceived and poorly executed, that exploit the myth of racial inferiorities. She looks toward psychology to make its greatest contribution now; namely to 'communicate the meaning of individual and group differences without accompanying value judgements or emphasis on superiority and inferiority.' I repeat, this is a book every professional should read. Not to read it—is dangerous."

VISION RESEARCH, an international journal

Editor: Dr. T. Shipley
Vision Laboratories, Bascom Palmer Eye Institute, University of Miami School of Medicine,
Miami, Florida 33136

- A. Vision Research is an international journal devoted to all aspects of vision. It is primarily concerned with the visual process—those phenomena that are invoked as a result of stimulation of the photoceptors. Emphasis is placed on retinal and perceptual studies, less so on the physical optics of the eye.
- B. The Journal carries reports on those phenomena that affect the quality of light on the eye, e.g. the spectral distribution of ambient light in different environments such as rivers, oceans, deep seas, woodlands, the passage of such light through the eye, and the correlation of such data with visual performance. Papers which approach the analysis of vision from the point of view of ecology and those relating to historical and philosophical aspects of perceptual and sensory studies are also published.
- C. Regular Features - Symposium issues, technical notes, letters to the editor and book reviews.

Published Monthly.

Annual Subscription: One year 1974; \$100.00 Two years 1974-75; \$180.00

Sometimes less is more

Sometimes it makes sense to use a 3½-pound, 700-page text in the introductory course. Sometimes it doesn't.

It doesn't when most of your students aren't psychology majors.

It doesn't when you assign other readings and activities.

It doesn't when you're teaching a semester or quarter course.

Less material here in fewer pages.

More stress on what is really important for a sound understanding of basic psychology—with more on human behavior than many texts. A scientifically sound, brief introduction to psychology that your students will understand and enjoy.

Clifford T. Morgan's A BRIEF INTRODUCTION TO PSYCHOLOGY

ORIENTATION AND FORM

by IRVIN ROCK

This book examines the problem of why things look different, and often become unfamiliar, when seen in a tilted or inverted position. The theoretical difficulty posed by this phenomenon has still not been resolved by psychologists, and, to account for it, Professor Rock proposes a new theory of form perception—one that differs substantially from currently favored views.

The Consolidated Roster for Psychology

A NEW LOCATOR-REFERENCE

Published as a Service to the Psychological Community
Compiled from the APA's 1972 Survey of Psychologists in the
United States and Canada

An alphabetized roster of over 45,000 professionals and graduate students, including all APA members and nonmember survey respondents. All levels of training and experience, a full range of employment settings, and all types of positions and specialty areas are represented.

Roster Contents include:

■ Alphabetized Listing

- Name
- Business or Home Address
- Business Telephone Number
- Primary Employment, including Graduate Study
- Two Psychological Specialties
- Highest Degree, Major Specialty Area, Institution and Year
- ABPP or ABPH Diploma Specialty
- State Licensure or Certification as a Psychologist
- Membership in the APA and CPA

■ Geographic Locator Index

United States, Canada and other Foreign Countries, organized by state or province, city, and primary employers. Private Practitioners and ABPP or ABPH diplomates are flagged.

■ Psychology Laws in the United States and Canada

A summarized presentation of the status of licensing and certification of psychologists.

■ Psychological Specialties

MANAGER MANPOWER UTILIZATION

A major multi-national manufacturing company which recognizes the value of its human resources has an immediate opening for a thoroughly experienced manager to direct its Manpower Utilization Program. Individuals should have a Ph.D. in Behavioral Science and a minimum of 5 years experience in Human Resource Development, applying the concepts of McGregor, Maslow and others.

Interested candidates are invited to forward resume summarizing education, managerial experience, salary history and requirement in confidence to MRRPB, 416-22-04, P.O. Box 1919, Detroit, Michigan 48231.

Self-Fulfillment & Aging Avocational Psychology in Managing a Tri-Powered Life

By G. L. Freeman (psycho-physiological researcher on original Yale Institute team, Prof. at N.U. and 'Starred Man' in the '30's; Lecturer-consultant for Cornell, New School, Magazines of Industry, Navy and SBA, Washington, avocations publicist on National Lecturer circuit in the '40's; funded researcher on aging from Guggenheim, SSRC, IMH, Cambridge, etc. and pre-retirement counsel for executives and professionals in the '50-'60's.) Retiring, himself, at age of 70 from heading American Life Foundation Study Institute, this is a life's-time study of three basic factors in man's life style.

Dr. Karl Menninger says, "Your *Energetics of Human Behavior via Homeostatic Mechanisms* is, for me, a Psychology Classic. . . . Looking forward to your study on aging."

About 200 pages, covering 40 areas like Body-Brain Development and Homeostasis; IVP Retirement Tests; Tests, Vocation & Avocation in Self-Fulfillment; Over-active Sex & Spiritual Arousal; Overt & Covert Measures in Aging; Gerontology's Life-span Increments, or Longer Life for What; 30 Selected Client-cases Speak for Themselves; Avocations as Re-creation; Appendices, Bibliography, Glossary and Indices.

A challenging 1,000 copy private edition here offered to researchers, therapists and counsellors at \$15.00 on a first-come-basis. Send check or Institutional order direct, American Life Foundation, Watkins Glen, N.Y. 14891. Full brochures available on request.

Current! Social Psychology:

New 1974

Understanding Human Interaction

Robert A. Baron, Purdue University
Donn Byrne, Purdue University
William Griffitt, Kansas State University

- **Contemporary:** The text deals with newer areas of interest: Prosocial Behavior, Modeling Processes, Sexual Behavior, and Environmental Factors.
- **Comprehensive:** "The text nicely represents the major areas of study. . . . The chapters tend to be very up-to-date while still thoroughly covering earlier work." — Robert Apsler, Boston University
- **Accurate:** "The standard of accuracy displayed by the authors, pretty much throughout the text, are high. . . ." — Tony Greenwald, The Ohio State University
- **Motivating:** Materials presented have been found, in actual teaching, to be interesting to students. Numerous photographs and cartoons help relate the findings and principles described to actual social situations. 1974, est. 544 pp.

Schizophrenia as a Life Style

ARTHUR BURTON, Ph.D., *formerly California State University*; JUAN J. LOPEZ-IBOR, M.D., *University of Madrid School of Medicine*; and WERNER M. MENDEL, M.D., *USC School of Medicine*

This is a book within the scope of the new radical psychiatry—its premise: that schizophrenia is a special state of being, amenable to behavioral change through psychotherapy and special group experiences. Like Laing and some others, the authors subscribe to the possibility of schizophrenia as a way of life—a life style. They offer certain alternatives to long-standing but inadequate theoretical formulations concerning schizophrenia, presenting theory from a new vantage point and with a view to a basis for treatment. 192 pp., \$8.50

Suicide and Crisis Intervention Survey and Guide to Services

SHEILA A. FISHER, Ph.D.

Foreword by NORMAN L. FARBEROW, Ph.D.

A unique synthesis of the techniques in use at suicide prevention and crisis centers throughout the country. The author, with a background of SPC and clinical work with troubled "hotline" callers, details the operation of the centers, from funding to followup services. Numerous appendices provide samples of worksheets, referral and follow-up forms, publicity, and a training manual. The relevance of the materials commends their use in social problems courses, as well as by mental health professionals and community leaders.

IN SIX PARTS: Introduction. The Human Revolution. Why 24-Hour Telephone Services. National Survey and Results. Selected Categories Concerning Operation Techniques. Summary and Conclusion. 288 pp., illus., \$6.95

The Two Faces of Symbolic Activity

When Howard Pollio of the University of Tennessee decided to write **THE PSYCHOLOGY OF SYMBOLIC ACTIVITY**, he wanted to avoid the pitfalls of other books on the subject. He wanted to show both sides of the story. And so *this* book deals fairly with the two most significant general approaches to symbolic activity—associative and information processing.

In the words of the author: “. . . I have tried to write each chapter as an ‘insider’ might. So, for example, if I were writing an associative chapter, I have tried to write as an associative psychologist might, and if I were writing an information-processing chapter, I have tried to write as an information psychologist might.”

Within the context of both of these approaches, Pollio treats the five topics of memory and forgetting, concept formation, problem solving, the development of thinking, and language and language use. And, in his exploration of the field, he deals directly as well as experimentally with each topic.

The book was written for junior/senior and graduate levels, and requires only introductory psychology as a prerequisite. (504 pp—1973—\$12.95).

SOME OTHER BOOKS OF INTEREST:

THE PSYCHOLOGY OF PERSONALITY by Wiggins, Renner, Clore, and Rose (705 pp, 95 illus—1971—\$11.25)

PERSONALITY AND PREDICTION: PRINCIPLES OF PERSONALITY ASSESSMENT by Wiggins (656 pp, 62 illus—1973—\$17.50)

THE ORIGINS OF ABNORMAL BEHAVIOR by Corah and Gale (448 pp, 5 illus, paperbound—1971—\$6.95)

FUNDAMENTALS OF BEHAVIORAL STATISTICS, SECOND EDITION by Runyon and Haber (351 pp—1971—\$8.95)

Everything You Need Is Already Within You. Discover It.

Arica is a totally new experience which combines the wisdom of the past with modern scientific knowledge to solve the problems of the present.

Based on a cohesive philosophy including theories of personality, motivation and consciousness, Arica focuses on developing and unifying the body, the mind and the emotions. It aims to increase vitality; eliminate negative emotional states and replace them with positive ones; increase mental clarity, and create a permanent higher level of awareness. Psychology Today has called Arica "the nearest thing we now have to a university for altered states of consciousness."

Arica is a system of Scientific Mysticism. *Scientific* because it requires no guru or belief structure. Instead each exercise is approached experimentally, as a hypothesis to be tested. *Mysticism* because Arica affirms that the goal of the individual is unity—unity within each person, between persons, and within the society as a whole.

Arica is an open center. Drop by an Arica Teaching House anytime for a visit or come to an Open Path Introduction every Wednesday evening held in major cities.

Experience Arica and begin to discover yourself.

The *American Psychologist* is the official publication of the American Psychological Association and, as such, contains archival documents as well as material submitted by authors. Articles should be timely and of broad general interest to psychologists of all scientific and professional persuasions. Manuscripts must adhere to the instructions on reference citations, preparation of tables and figures, manuscript format, etc., as described in the *Publication Manual of the American Psychological Association*. Manuscripts that do not conform to the style set forth in the *Manual* will be returned for revision. When in doubt about practices of the Journal, authors should examine a recent issue.

Articles under consideration or accepted by another periodical of general circulation are not acceptable. Also, articles accepted for publication by this Journal may not be reprinted elsewhere without APA permission. Comments should be submitted no later than two months from the date of the issue containing an article on which comment is made in order to ensure timeliness.

Submit manuscripts in triplicate, accompanied by a 100-120-word abstract, to Kenneth B. Little, American Psychological Association, 1200 Seventeenth Street, N.W., Washington, D.C. 20036.

Statements contained in the *American Psychologist* are the personal views of the author(s) and do not constitute APA policy unless so indicated. APA reserves the right to edit all copy and to refuse ads that are not in consonance with the principles of Title VII of the Civil Rights Act of 1964 (Equal Employment Opportunity).

Written permission must be obtained from the APA for copying or reprinting text of more than 500 words, tables, or figures. Address requests to the Permissions Office.

The American Psychological Association, founded in 1892 and incorporated in 1925, is the major psychological organization in the United States. The purpose of the APA is to advance psychology as a science, and as a means of promoting human welfare. It attempts to accomplish these objectives by holding annual meetings, publishing psychological journals, and working toward improved standards for psychological training and service.

In addition to the *American Psychologist*, the Association publishes 13 other journals: *Contemporary Psychology*, *Developmental Psychology*, *Journal of Abnormal Psychology*, *Journal of Applied Psychology*, *Journal of Comparative and Physiological Psychology*, *Journal of Consulting and Clinical Psychology*, *Journal of Counseling Psychology*, *Journal of Educational Psychology*, *Journal of Experimental Psychology*, *Journal of Personality and Social Psychology*, *Professional Psychology*, *Psychological Bulletin*, and *Psychological Review*. The APA also publishes *Psychological Abstracts*, the *APA Monitor*, a monthly *Employment Bulletin*, the *Biographical Directory*, the *Convention Proceedings*, the *Convention Program*, and the *Catalog of Selected Documents in Psychology*.

What Psychology Is About

D. O. HEBB *McGill University*¹

For a quarter century or more, ever since the end of World War II, psychology has been growing fast in ideas, methods, knowledge—data all over the place. To maintain perspective is difficult enough, but the difficulty is increased by our publications. It is bad not to see the wood for the trees, but worse not even to get to see a real tree because you're lost in the bushes, the undergrowth of insignificant detail and so-called replications, the trivial, the transient, the papers that haven't an idea anywhere about them. This, one must find his way through also. There is a useful maxim that I owe to my colleague Reg Bromiley: What's not worth doing is not worth doing well. The journals are full of papers that are very well done and will not be heard of again. One well-known journal almost makes them its specialty. For all these reasons or in one or another of these ways it is easy to lose sight of the fundamentals of psychology as it stands today.

It's hard to keep up, even in your own specialty. How can you hope to know what's going on—or not going on—in someone else's? But if you don't, if you haven't some general idea at least of others' work, you lose perspective. Psychology is not clinical psychology; it is not physiological psychology; it is not social or comparative or developmental or human experimental psychology. It is something more, comprising all those lines of approach to the central mystery. When the clinical psychologist forgets that he is a psychologist too, what does he become? If he's real good, he becomes a second-rate psychiatrist (since he lacks medical competence). When the physiological psychologist forgets it, when he slides downhill to become an expert on the red nucleus or the cingulate gyrus or the *cornu ammonis*, for its own sake and not as a

key to an understanding of behavior, he takes the easy path to simpler problems. He may be a good physiologist, but he's not a psychologist any longer. Psychology is tough, and it's important.

The current flood of papers, that deluge of data, leads us to forget fundamentals. I meet graduate students in seminar each year. They come from good schools and they've had as good teaching as there is. And most of them have no clear ideas about the relation of mind to body, or about consciousness, or what thought is, or free will. I didn't say good ideas (those are the ones I agree with); I only said clear ideas. They seem not to have been led to think about such problems. In seminar they hope the problems will go away if they just keep quiet about them. A majority, I would say, have no clarity even about the heredity-environment question; and this, ladies and gentlemen, I am inclined to give *you* the discredit for, since the literature suggests that some of you don't either.

I begin to sound like a prophet in ancient Israel, misanthropic, damning everybody—like Amos, "Woe unto them at ease in Zion!"—or a certain later prophet, "Woe unto you, scribes and pharisees!" Especially the scribes.

The questions of mind, free will, thought—these are not unimportant matters, not insignificant. That book of Fred Skinner's (1971) *Beyond Freedom and Dignity* has demonstrated that they have real practical meaning. Skinner thinks the questions are important, and so do I. You no doubt realize that my answers differ from his, but I applaud his concern with fundamentals. And some of the criticism of *Beyond Freedom and Dignity* shows (like some of the criticism of Arthur Jensen) that there are questions on which some human psychologists—you know, the ones who don't work with animals—feel no need to think. They have ready-made answers.

One of those ready-made positions goes back to Thomas Jefferson, who swore "eternal hostility" to any form of "tyranny over the mind of man." Skinner proposed to make people want to be good—and caught hell for it. He was told it is wicked to

¹ This article was the APA Invited Address presented at the annual meeting of the American Psychological Association, Montreal, Canada, August 29, 1973.

The critical advice of Dalbir Bindra and Virginia Douglas is gratefully acknowledged.

"manipulate" the minds of others, and wicked to do anything to interfere with full freedom of choice. This is evil; this is something that no good humanistic, democratic, libertarian would ever do? Such statements are pure unthinking nonsense.

For what is a moral education? The very psychologists and philosophers who talk most about freedom are the ones who tolerate no nonsense from their children or their students, in moral and political questions. A liberal, democratic, moral education sets out, rightly, to *remove* freedom of choice from a child's mind in moral questions. The tyranny Jefferson objected to was imposing ideas *he* didn't agree with (and *we* don't agree with today, either). Imposing ideas *we* agree with is OK, and necessary too. Education is in a bad way if a boy on reaching maturity has to sit down and argue out the question before deciding whether race prejudice is a good thing, or cruelty to animals, or fascist governments, or "Watergating"—or if a girl leaving home has still to figure out whether a career in shoplifting or prostitution would be a good idea. Impose ideas? Try to limit freedom of choice? Of course we do, all of us. Skinner's critics will say at once that this isn't at all what they were talking about. Maybe so, but it's clear they didn't stop to think before giving out the word, and I still don't see what's wrong about making people *want* to be good—if we could only make it work!

* * * * *

I am gradually getting around to an answer to the question, What is psychology about? by first telling you some things it is not or should not do. I have said that psychology is not one of the many narrow specialties that, between us, we cultivate. It is more than any one of them. It is important for the welfare of psychology to keep reminding oneself about fundamentals and to *think* about some of those issues. Now, what psychology is.

Psychology is a biological science. Before you clinical and social and vocational guidance types get up and leave, hear me a little further. I think anyone will agree—including the monkey trainer, the rat-brain plumber, and those who write down baby talk—that the urgent psychological problems are *social* and *clinical*. These are the big ones on which more light is needed to promote human welfare. These are the problems of prejudice and social conflict—at the worst, war—and the problems of mental disorder, neurosis and psychosis. Knowing more about the rat and pigeon is—I personally am sure—a step toward understanding man; maybe

for practical purposes it's a necessary step; but it's peripheral; it's a means, not an end. Memory, however studied, is an essential component of behavior—but one component only. There is a larger picture to take account of, and its social and clinical implications are vital.

So how is social psychology part of a biological science? I am not talking about the social insects, or schools of fish, or dominance in baboons—though these studies are enlightening too—but about man's social behavior looked at in the light of evolution. Man is a social *animal*. His society is complex, the experience and learning of the child growing up in it are complex, and so it is hard to trace the origins of adult human social behavior. With animals, there's a better chance. Also, we are so habituated to human behavior that it is hard even to see some of its outstanding characteristics. Which of us, for example, if asked to list the predictable features of man's behavior would include sleep—an instinctive pattern if there ever was one? A comparative perspective might not correct that particular blind spot, but it does help with others.

Some students are still being taught that man by his nature is selfish; however, 35 years ago Crawford and Nissen's chimps showed that that is false. Students are still being taught, or allowed to think, that man dislikes work; Harlow's monkeys showed the falsity of that idea 25 years ago. Students are still being taught that hostility has to be acquired, from bad teaching or from job competition. From that comes the dangerous doctrine that if there is no competition and no bad teaching, there will be no prejudice. That disastrous misconception could not survive if you observed how a group of "higher" animals—higher in evolutionary status, not in rationality!—treats a stranger in their midst. A dog doesn't have to be taught to growl at strange dogs; the monkey doesn't need to learn to drive off the newcomer, who sins only by being unknown. And this irrational emotionality increases with evolution, instead of decreasing. *Man is a social animal*; seen in that light, both virtues and faults make more sense.

There are other clarifications from work with nonhuman animals that tend to be forgotten in the human social situation. One example concerns the problem of language and language learning. The psycholinguist might have been farther ahead if he had recognized that language is a species-predictable form of behavior, that is to say, instinctive behavior, and recognized also that instinctive behavior in birds and mammals isn't merely a matter of

heredity. Learning is part of instinct too. The whole problem would have been clarified by reading a 20-year-old paper, "The Descent of Instinct," by Frank Beach (1955). Those who know no history are condemned to repeat it.

The social psychologist must recognize that there is a definite, definable sense in which he is a biological rather than a social scientist. He doesn't really belong in the same grouping with the economist, the anthropologist, and the political scientist—not even with the sociologist—if only because of that preoccupation with learning that all psychologists share in one way or another. No psychologist of course *agrees* with any other psychologist, but they all have strong views about learning, reinforcement, and John B. Watson.

More fundamental, perhaps, is the fact that the social psychologist approaches social phenomena from the point of view of the participating individual, instead of regarding the group as an entity. As evidence, consider the traditionally close relation between *social* and *personality* as fields of teaching and research; personality is by its essence the study of the individual. Add to all of this that social psychology has become experimental—not really true of any other social science—and you can see why it is not unreasonable to regard it as a biological science as well as a social one.

And clinical psychology too, which has always had an important connection with the biological field. I may remind you that the definitive demonstration of a breakdown due only to experiential pressure, on an otherwise normal organism, is the experimental neurosis that was first observed by Shenger-Krestovnikova, in Pavlov's laboratory. Perhaps you thought, when I said that clinical psychology is a biological science, that I was going to say that mental disorder is all due to heredity—or brain tumors. I am really not as simpleminded as that. It's true that psychosis sometimes originates in some sort of lesion in the brain, but only sometimes. And it's never heredity by itself—or experience by itself, either. Always, always, it's an interaction of heredity with environmental agents, or—a slightly different proposition—constitution interacting with experience. Even that classical Pavlovian demonstration, the experimental neurosis, was induced by experience but was a function of heredity, too. Only some dogs broke down as a result of the perceptual conflict. The biological view doesn't mean forgetting Freud—after all, Freud and animal-rearing experiments are in full agreement about the lasting effects of the early environment.

And behavior therapy: It takes different forms today, but all goes back to Skinner, the rat, and the pigeon. And behavior therapy today is radically affecting clinical procedures.

The biological view is a corrective against going to extremes. No one in touch with animal work today is likely to overlook the role of experience in mental disorder; even when a constitutional disturbance is the principal cause, experience still plays a part and must be dealt with: Supply the missing adrenal cortical hormones, and you may still have to use psychotherapy to get the patient back on an even keel. And the biological view will remind you that there are constitutional factors involved, to a major degree, in many cases of neurosis and psychosis. How anyone can say that there is no mental illness, that neurosis is all a social fiction, I can't see. Anyone who observes the suffering that can go with an endogenous depression must know that is false. Give the devil his due: There are medical elements in many cases, and chemotherapy is frequently essential. The psychological elements are there, too, and we may have to fight to have them recognized, but you can spoil a good case by overstating it.

Anyway, what all this says is that seeing psychology as a biological science need not prejudice a soundly psychological point of view; and it does help, sometimes, to keep one from talking nonsense.

* * * * *

There are many people who are unhappy about the course of modern psychology, and, I regret to say, this includes some psychologists. The objectors do not want an objective science, but a sort of self-contemplation. Not the hard-shell introspection of Titchener, Külpe, and Wundt, but something sloppier. They tend to be dualists at heart, and they dislike what they think of as the materialism of experimental psychology; and they consider that psychology's true business is not with cats or monkeys, not brain lesions, not the use of tachistoscope or the analysis of variance. The more profound human experiences are what we should be working on. They want us to deal directly with the mystery of existence *now*. Some of this is simply antisience—antisience of any kind—which we needn't bother with here. But when someone thinks a science can be run that way, there is much to be said.

Subjective science? There isn't such a thing. Introspectionism is a dead duck. It is theoretically impossible: See Charles S. Peirce, America's great-

est philosopher, 100 years ago; Gilbert Ryle, Oxford philosopher; Garry Boring, *Mr. Psychology*; and George Humphrey, American-trained Oxford Professor of Psychology—a pretty distinguished lot for you to disprove if you think introspection is still in business. And then, if you do disprove them (nobody has tried so far), you still have to explain how come, if that subjective approach is the true path to a knowledge of man, it has achieved so little. What can you point to that either Wundt or Titchener left behind him, what light on the problem of mind and thought and feeling? Külpe, in a way, did better, for his work pointed straight to the proposition that psychology is objective, not subjective. William James is not an argument for subjective psychology; he took introspection for granted, but search his pages and you'll find precious little introspective data. Introspecting was *not* what James did.

And Freud—you realize of course that Freud's method with the unconscious was, by definition, objective—the study of that part of mental activity that the patient *cannot* report. Piaget—objective method; Lashley on serial order and thought—objective method; Köhler on insight; Lewin on leadership; Harlow on love—all objective. What is there to cite as a contribution from subjective method that can be put beside their work?

And the same question must be asked about humanistic psychology. What is the payoff? What is its contribution to knowledge? I sympathize with the feeling that scientific psychology, as far as it has gone today, leaves much to be desired in the understanding of man and has little to tell us about how to live wisely and well. I am inclined to think that scientific psychology will always be incomplete in that sense. But the remedy is not to try to remake a science into one of the humanities. Humanistic psychology, I think, confuses two very different ways of knowing human beings and knowing how to live with self-respect. One is science; the other is literature. A science imposes limits on itself and makes its progress by attacking only those problems that it is fitted to attack by existing knowledge and methods. Psychology has made much progress in this century, and the rate of progress is accelerating, but it is limited and must be limited if it is to continue its progress—limited in the questions it can ask, but sure in its results.

The other way of knowing about human beings is the intuitive artistic insight of the poet, novelist, historian, dramatist, and biographer. This alternative to psychology is a valid and a deeply penetrat-

ing source of light on man, going directly to the heart of the matter. If you refer to literature as a source of knowledge to a scientific type, he'll laugh at you. How can a novelist or a poet—a poet for god's sake—make discoveries? How can *he* have a knowledge of man that science hasn't? Science is the up-to-date thing; the paraphernalia of experiment and controlled observation and analysis of variance are the ways to find things out. Pick and shovel are out of date, now that we have bulldozers? But you can do things with a pick and shovel that you can't with a bulldozer; a man on foot can make observations that you can't make from a limousine. I challenge anyone to cite a scientific psychological analysis of character to match Conrad's study of Lord Jim, or Boswell's study of Johnson, or Johnson's of Savage.

It is to the literary world, not to psychological science, that you go to learn how to live with people, how to make love, how not to make enemies; to find out what grief does to people, or the stoicism that is possible in the endurance of pain, or how if you're lucky you may die with dignity; to see how corrosive the effects of jealousy can be, or how power corrupts or does not corrupt. For such knowledge and such understanding of the human species, don't look in my *Textbook of Psychology* (or anyone else's), try *Lear* and *Othello* and *Hamlet*. As a supplement to William James, read *Henry James*, and Jane Austen, and Mark Twain. These people are telling us things that are not on science's program. Trying to make over science to be simultaneously scientific and humanistic (in the true sense of that word) falls between two stools. Science is the servant of humanism, not part of it. Combining the two ruins both.

* * * * *

So, then, finally, what is psychology about? And the answer I give you is one I got from K. S. Lashley: Psychology is about the mind: the central issue, the great mystery, the toughest problem of all. I grant that psychology is concerned with other matters, subsidiary questions; in fact, I have just been saying that a science must move slowly and can't hope to go right to the heart of things. There are many subsidiary questions to be clarified before we will have final answers to the central question, before we understand the operations of mind—if we ever do really understand them. Nevertheless, there are some answers possible that were not possible when Lashley first saw a set of Golgi slides of the frog brain and thought it might be possible to find

out how the frog works. We still do not know how the frog works, let alone man. In fact, the problem looks tougher now than it did to Lashley in 1910, but we have made some advances, and there are some things one can say—that a biological science should say—about the human mind.

It is hardly necessary to say that the mind, for Lashley, was not a spirit held in the body. Biological science long ago got rid of vitalism. The idea of an immaterial mind controlling the body is vitalism, no more, no less; it has no place in science. I know that many of you are dualists and *do* believe that the mind is something other than brain activity. Indeed, it is conceivable that you are right. There is no way of proving the null hypothesis, no conceivable way of proving the nonexistence of something as slippery as the soul. But I put it to you that the null hypothesis can be disproved. If you believe in the existence of a spirit that guides man, the scientific and logical procedure for you is to assume its nonexistence, with the expectation that some day it will be found that this "null hypothesis" is insufficient. That is, if you will take as a working assumption that there is no soul, you may one day show that there *is* one. This means that believers and unbelievers can avail themselves today of the same working assumption, of monism instead of dualism. Anything else, today, is not science.

Mind then is the capacity for thought, and thought is the integrative activity of the brain—that activity up in the control tower that, during waking hours, overrides reflex response and frees behavior from sense dominance. I do not propose here to refute, once more, the Watsonian notion that thought is muscular activity, mainly of the vocal organs. Walter B. Hunter, a tough, behavioristically minded scientist, showed how to refute it in 1913. The delayed-response method shows that response is not controlled by sensation alone. There are other demonstrations of the same thing, and the learning theorist who does not recognize it is simply refusing to face reality.

The fact of thought as a semi-independent factor in behavior is something that anyone working with mammals is familiar with. It is summed up in the third law. (The first law is, If anything can go wrong in the experiment, it will; the second law, Training takes time, whether or not anything is learned; and the third law, Any well-trained experimental animal, in a controlled environment and subject to controlled stimulation, will do as he damned well pleases.)

That's an old joke and you may be bored by hearing it again. But it has a significance that may not have struck you. What the third law is talking about is the fact of free will in animals—higher animals, at least—and what it says is that free will is not some fancy philosophical abstraction or something J. B. Rhine thought up, but an ordinary, familiar, biological phenomenon, a product of evolution. Free will is not a violation of scientific law; it doesn't mean indeterminism; it's not mystical. What it is, simply, is a control of behavior by the thought process. Not all behavior is so controlled, even in the higher animal, reflexive response being excluded. But most behavior of man or monkey or ape is under a joint guidance by sense input and the immediately prior pattern of cortical activity; and the cortical component in that control is free will. The idea that free will means indeterminism is simply a misunderstanding.

Let me take a minute more on this, because it's important. I am a determinist. I assume that what I am and how I think are entirely the products of my heredity and my environmental history. I have no freedom about what I *am*. But that is not what free will is about. The question is whether my behavior is entirely controlled by present circumstances. Heredity and environment shaped me, largely while I was growing up. That shaping, including how I think about things, may incline me to act in opposition to the shaping that the *present* environment would be likely to induce: And so I may decide to be polite to others, or sit down to write this article when I'd rather not, or, on the other hand, decide to goof off when I should be working. If my past has shaped me to goof off, and I do goof off despite my secretary's urging, that's free will. But it's not indeterminism.

* * * * *

Free will thus has a physiological basis, in the relative autonomy of the activity of the cerebrum. Here again is evidence of the way in which physiological and biological conceptions can be clarifying, as we think about the evolution of that equipment up in the control tower—between the ears—and how it works. One would think consequently that physiological psychologists should be first among those who see man as a whole, those who keep us reminded of the main objective: an understanding of that integrative function of the cerebral cortex that makes man what he is. And are they?

Mostly, no. Mostly they are afraid of theory. Mostly they are even worse at keeping an eye on

the ball than the paired-associate learners and the analysis of variance experts. Mostly. But some exception must be made for those whose work takes them into the neurological clinic and exposes them to the real problems of real people. A couple of Montreal examples are Brenda Milner, on the devastating effects of total loss of capacity to form new memories, and Ronald Melzack on pain—pain being pretty good at bringing out man's humanity, in one way or another. But the outstanding example for my present purposes is the work of Sperry and Gazzaniga on split-brain patients. For any one of you who is concerned about the mind-body question, for anyone who proposes to philosophize about the fundamental nature of consciousness, that work is essential. Read that if you never read anything else about the brain. I speak to the dualist especially, the one who considers that consciousness can't be something produced by the brain. Sperry (1968) made a case for his conclusion that longitudinal sectioning of the human brain into left and right halves has the result that the patient has two minds: a left-hand mind and a right-hand mind, each with its own separate purposes, thoughts, and perceptions. The surgeon's knife can cut brain tissue, no problem there: Can it also cut an immaterial mind in two, make a longitudinal section of the ghost in the machine? Today, no one, psychologist, philosopher, neurologist, or humanist, is entitled to an opinion on the mind-body question if he is unfamiliar with the split-brain procedure and its results in human patients.

I don't know, in general, that the objective-biological-physiological approach is always clarifying, but I do know that we have nowhere else to look for ideas about the mechanics of thought. The ideas are speculative, certainly, but when science stops being speculative it stops being science and becomes technology. As an example we can take a long-standing puzzle concerning creative thought and see whether from an objective point of view it really need be so puzzling. What I'm talking about is the report by certain poets and mathematicians and scientists especially, that they have suddenly on occasion been given answers they didn't work out themselves. The poet finds himself listening to a poem, or part of a poem; the lightning calculator hears a voice telling him what the next step in calculation should be; the mathematician gives up on a problem and then when doing something else finds that he has the answer, sometimes not the kind of answer he expected; the scientist gets the solution to his problem in a dream. Now this must seem a

disconcerting sort of thing to happen to one, and it's hardly surprising that some of those to whom it has happened have regarded it as a form of supernatural visitation. William Blake considered that some of his verse was dictated to him by his dead brother. A. E. Housman reported, of a particular poem of four stanzas, that two of the stanzas "bubbled up" into his mind; a third stanza came "with a little coaxing"; but then, he said, the fourth stanza, necessary to complete the poem, did not come: "*I had to turn to and compose it myself, and that was a laborious business.*" Housman doesn't say where the first three stanzas came from, but he's quite clear that it wasn't him that did it. It's hardly surprising, when we consider this sort of thing, that some of the great religious authors considered that their words came direct from God.

Now, today, God is less likely to get the credit. When the artistic or intellectual product takes one by surprise, a different source is apt to be thought of: namely, the unconscious. For a good example of this line of thought I refer you to Jacques Hadamard (1954), who put the argument beautifully, mainly on the basis of the earlier argument by Henri Poincaré. I won't labor Poincaré's report, which you probably remember: In brief, he sweated over a problem and finally gave up—for the time being at least—and then, unexpectedly, out of the blue, found the answer in his thoughts and made one of his great mathematical discoveries.

Poincaré, and following him Hadamard, discussed this phenomenon as proof of the existence of the unconscious: not as an annex or department, but like a separate mind, richer and more powerful and more creative than the mind we are conscious of—or the one they think we are conscious of—and not at all subordinate. And this seems today to be established doctrine. A science writer says the great mathematicians and scientists are the ones who have learned "how to tap the unconscious"—just like tapping a barrel of beer at a picnic. Literary critics know all about the unconscious. There is a debate for example about Coleridge, and whether maybe too much credit is being given to his unconscious for *Christabel* and *The Rime of the Ancient Mariner*. Maybe Coleridge himself should have some of the credit.

That's getting pretty silly. But we can sympathize a little when we remember how strange some of the reported experiences must seem. Imagine for a moment that you are a theoretical physicist looking for a birthday present for your wife when you suddenly realize that $H \psi_i \text{ sub } n$

must be identical with *E sub n psi sub n*, coming out of the blue. A thing like that might shake anybody. Or you drink a bottle of beer, go for a walk, and with equal suddenness find yourself the possessor of half a poem, all ready to write down and only needing a little work from you to complete it. Or, like Blake, you hear something like "Tiger, tiger, burning bright/ In the forests of the night," and so on, spoken in your dead brother's voice. Mysterious, puzzling, even frightening.

But what is the nature of the mystery? What is it that is puzzling? Why does this sound so surprising? Similar things in fact happen to us ordinary mortals all the time, only on a smaller scale. You try to think of a way to describe some experience or other, with no success, and then the right words occur to you at the dinner table, or in the john. Trying to repair some gadget or building a model of some sort you are momentarily balked, go on to other things, and then suddenly a solution to the difficulty "occurs" to you, as we say. But this is so common it doesn't seem mysterious at all. So, in the first place, the mathematical and the poetic phenomena may be noticed only because they're so extensive. A poet, for example, isn't surprised when a single happy word or phrase occurs to him—that's what it means to be a poet—but he may be surprised when bigger chunks of verse are presented to his thought.

But the main reason is that we're all brought up to think we know our own minds and what they're up to at any moment. Thus, it's an exciting and romantic idea that each of us has within him an unknown entity, the unconscious, that makes us do things we mightn't otherwise. Freud's unconscious was mostly a doer of dirty deeds, but it's even more romantic now to think of it as something with great intellectual and aesthetic powers. None of this need be rejected. I've already referred you to the eminent psychologists and philosophers who have, each in his own way, concluded that there is no *conscious* mind in Herbart's sense and in Freud's. What goes on we know something about, but only incompletely and by inference, not by direct inspection.

From that point of view, the sudden occurrence of a new idea or new cognitive program is intelligible enough, at least in principle and theoretically. (The details will take a little longer.) I assume that a concept, an idea in the ordinary sense of the word, has the same sort of structure as a percept. We know that a percept of a table, or a car, or a book, or any such familiar object, is per-

Figure 1. Diagram of a new creative idea.

ceived and imaged as a series of part-perceptions, with separate visual fixations. If a new creative idea is also a sequentially organized complex, certain things become more intelligible. Consider the diagram in Figure 1, in which each letter represents a possible component of the new idea, the components occurring independently and more or less at random. For the problem solver, these are data and ideas originating in the "preparatory period" emphasized by every writer on this topic; for the poet, they are the result of that intoxication with words, and verbal imagery, that poets are known for. These separate ideational elements fire and subside, fire and subside, until the crucial combination occurs. The combination is represented in the diagram by K-L-M, firing in that order. This is the new scientific idea or the happy poetic phrase.

This model of creativity obviously explains the chance element in discovery, thoroughly documented in the history of science. But it also explains something else: why forgetting a problem might be a positive help—why "to invent, you must think aside." The sequences of ideational components cannot be really random, because of old habits of thought; and if L is strongly associated with, for example, R, the vital sequence K-L-M, without R, is not likely to occur. Thus, we have Claude Bernard's dictum that "those who have an excessive faith in their own ideas are not well fitted to make discoveries," and thus we can understand why, on occasion, a deliberate setting to one side, a deliberate cessation of effort to solve a problem, may lead to the solution unexpectedly. (This, of course, would not be necessary if you knew in advance which are the right ideational elements, but,

of course, you never do, in the truly creative act—it's full of surprises.)

The question that one is apt to ask next is, How does the thinker recognize the creative combination when it occurs? But this is not the right way to ask the question. The real question is, What is its special property? What makes K-L-M in the diagram hold together, instead of just disappearing as the other adventitious combinations do? And there is no answer available. We must suppose, from the subject's behavior at this point, that the combination is one that has some special excitatory value for what is called "the prepared mind"—but not for others. What the physiological basis is, is not apparent. In some way the new combination, the creative idea, is one that can take control of the stream of thought and of behavior.

When we ask what the *psychological* characteristics are of the idea that can grab thought in this way, an interesting point emerges. We usually think of the creative solution to a problem as one that affects practical affairs: The thinker can build a new kind of bridge, or make better bread, and so on. But, in fact, the idea that results often has no such practical significance, but is held as a result of its effect on the thinker's further thought. I have no intention at this stage of trying to trace out the ramifications of this effect, but I wish to draw your attention to one particular aspect that hasn't had enough attention in psychology. This is the attraction of the mysterious, the unsolved problem, the far-out idea that seems to contradict existing knowledge. Such ideas are not at all foreign to science and mathematics. As Barber (1961) has shown, the great new ideas of science at first looked preposterous to professionals as well as to laymen, but then when their organizing and clarifying effect was seen, they became commonplace.

But we can take this further and see an aspect of human motivation that has not been adequately dealt with. The far-out idea can be attractive in and of itself, apart from any clarifying effect. The fact of religion, the universality of strongly held dogmatic belief independent of any need of evidence to support it, is a fundamental fact, species predictable. It is the "will to believe" of James, and it seems that belief becomes stronger, not weaker, when it meets a contradiction. Contradictions, and the preposterous, seem to have an inherent attraction. The relation to Festinger's "cognitive dissonance" seems obvious.

There are parallel phenomena in behavioral science. I venture to say that old-time psychoanaly-

sis, like Christianity, had its startling success *because* its central doctrines were so preposterous. The parallel with religion is reinforced by the frequency of schisms and sects and vicious disagreements about hairsplitting points of doctrine. A less dramatic example, but one I think in the same pattern, is the black box learning theory of 1945 with its denial of an intracranial determinant of behavior, that is, a denial of thought, along with persistent refusal even to discuss opposed evidence such as Hunter's delayed response, or the phenomenon of mental set. And—still current and very much up-to-date—there is the example of parapsychology.

I do not say that life after death is inconceivable, and I do not say that telepathy is inconceivable; I do say that the supporting evidence falls far short of what would be needed to establish such obviously important propositions. A case can be made that it is the romantic, mysterious nature of extra-sensory perception that attracts. Telepathy at short range is conceivable, barely, on the ground that the living brain is always broadcasting, though there is absolutely no suggestion of how it might have its effect on a second brain. But this becomes less conceivable when we are told that distance makes no difference to the transmission. And clairvoyance: Where does the energy come from in that case? Or in psychokinesis? I could agree that these doctrines had a rational origin, an evidential basis, if I saw the parapsychologist worry about the physiological implications, or about the problem of the conservation of energy. He is saying that there are big holes in physiology and physics. Set aside precognition, the very idea of which contains a contradiction, and one must still have doubts, to say the least, about parapsychology, as long as it maintains that bland disregard for the physical implications. Science, including biological science, is *one* body of thought.

I may have missed someone in these unprovoked aggressions, in this catalog of gripes, but it's time for me to wind it up. I have argued that psychology is a biological science, including its social and clinical wings; that a science is self-limiting, holding more or less strictly to its own narrow modes of procedure; and consequently that mixing psychology up with other ways of knowing human beings—the literary and artistic way—is to the detriment of both. We must honor the humanities, but a science cannot imitate them. I have answered the implied question, What is psychology about? by saying that its central concern must be man's mind

and thought. Each of us has his own avenue of approach to that understanding, which we must approach by degrees. It is a far prospect, and in the meantime we have to keep on with the study of memory, perception, psycholinguistics, fear, and so on and so forth; but it may be disastrous in the long run for psychology when the specialist digging his own path deeper and deeper loses sight of what others are doing in other fields and so loses an invaluable perspective.

Supplement to Listing of APA-Approved Doctoral and Internship Training Programs

The Committee on Accreditation announces the following changes in the list of APA-Approved Doctoral Programs in Professional (Clinical, Counseling, and School) Psychology and in the list of APA-Approved Internship Programs in Professional Psychology. These changes update the listings published in the September 1973 *American Psychologist* (pp. 844-848). Complete lists are available on request from the APA Educational Affairs Office.

FULLY APPROVED DOCTORAL TRAINING PROGRAMS

University of Illinois (Clinical PsyD)

Some Perspectives for Industrial Psychology

EDWIN E. GHISELLI *University of California, Berkeley*¹

We industrial psychologists are a curiously introspective lot about our professional selves. For some reason or another we are greatly concerned about what we are doing, how we are doing it, and what we ought to be doing. In the very early days of industrial psychology, our folk heroes, people such as Viteles, Link, Bingham, Paterson, and Burt, all had their say about the role of industrial psychology and what it should be concerned with. Those of us who formed the next generation continued to insist on telling each other at great length who we are, what matters we ought to consider, and how we should do what we do; and the current generation has continued this custom of a periodic auditing of our field.

I propose now to continue this custom, and I shall discuss a rather mixed bag of matters that I believe we as industrial psychologists ought to think about. I shall consider some notions about the nature of the variables we use, the study of organizations, the role and nature of theory, the permanence of facts, and individual differences and individuality.

The Nature of Variables

As industrial psychologists we are concerned with various aspects of workers' behavior, together with the many factors that are related to, or determine, it. We examine the sundry variables that are manifestations of workers' mental life or that bear on it, ascertaining their interrelationships and the effects of one upon another. Let us think a bit about these variables.

We become so involved with the psychological variables that we propose as pertaining to occupational behavior, that we come to think and act as though those variables have a certain truth—a

reality of the same order as that of physical variables. We fail to keep in mind that psychological variables are intellectual constructs, mere conventions. Generally, to be sure, they are useful conventions, for they provide meaningful descriptions of human behavior. Nevertheless, we must recognize the fact that the psychological traits and properties we formalize have a will-o'-the-wisp nature; perhaps they are there and perhaps they are not.

Each of us tends to see the greater importance and relevance of certain psychological variables over others, and we go to great lengths to persuade our colleagues of their significance. This is not to say that the variables each of us finds to be of compelling interest are entirely unique, for this is not the case by any means. There is a great similarity in our training, and we are all the audience of the same professional and scientific conferences and publications. Consequently, it is not surprising to find that there is some sameness among us in the particular variables we perceive as pertaining to people.

What I am saying is that when we set about examining workers' behavior, the particular variables we distinguish as being relevant emerge from our individual notions about the psychological nature of man. These notions reflect our various individual frames of reference, and since we have very similar backgrounds and operate in quite similar intellectual environments, our various frames of reference are quite similar. The extensive commerce we have with each other in the exchange of information and ideas has almost rigidly institutionalized the sorts of variables that we permit each other to use.

We psychologists are not the only people who speculate about the essence of human nature, nor are we the only ones who have insight into it. The ordinary man constantly observes the behavior of his fellows and ponders about the factors that determine it. As a result of his experiences with his fellow workers, together with the pains and joys he himself has experienced in connection with his job,

he develops some quite shrewd notions. The proverbial philosophizing of the taxi driver is not entirely trivial, nor are the chattering comments of the coffee shop waitress absolutely witless.

The working Jill and Joe fend for their existence in the harsh realities of the world. The fact that they survive and pursue useful careers in such a demanding social environment is testimony to the fact that they possess considerable insight into the varieties of behavior human beings manifest and into the sorts of factors that determine this behavior. The layman's ideas about man's mental machinery are by no means without substance, and by ignoring them it is quite possible that we are missing a truly rich lode.

In formal interviews and informal conversations with people about work and matters pertaining to it, my attention has been drawn to a number of variables that describe significant aspects of the behavior of workers, that I had just not thought of before, and that I found both interesting and useful. As an example, let me cite a property which might be called the *hobo syndrome*. This syndrome can be defined as the periodic itch to move from a job in one place to some other job in some other place. I have seen this syndrome in all manner of people, from those engaged in occupations that require little by way of training or skill, to those in substantial managerial positions. This urge to move seems not to result from organized or logical thought, but rather would appear more akin to raw, surging, internal impulses, perhaps not unlike those that cause birds to migrate. Floaters readily provide socially acceptable explanations for their peripatetic activity, but under careful examination these explanations turn out to be little more than rationalizations. The simple fact is that after being in one place for a matter of months, or perhaps a year or so, depending on the strength and periodicity of his itch, the individual is impelled to pack up and move to another place and another job.

Folk songs often are authentic expressions of a people's concerns, characteristics, and motives, and the variable I am trying to particularize for you is often described in them. In the ballad of the hobo, the lay of the wandering cowboy, and the song of the itinerant worker, country and western music fully attests to the genuineness of this recurrent itch to move on. Very likely, an analysis of the content of work songs would give industrial psychologists other new and interesting insights into the behavior of workers. In any event, many of the baffling cases I have come across in interviews

that I have had with workers about why they left their jobs are resolved when I consider the possibility of this hobo syndrome as a factor that determines behavior.

Organizations

I now turn to my second topic, the investigation of organizations. Today we call our field industrial and organizational psychology in order to acknowledge that we are concerned with men and women in a particular kind of social setting, the business or industrial organization. We have established new journals and have produced new and different sorts of books as outlets for our surging research and thinking about organizations. Yet I believe we have just begun to recognize a few of the many facets of the matter and to empirically explore them. To be sure, we are showing more and more breadth and sophistication in the ways in which we view our problems by considering the social setting wherein Jill and Joe labor, but I do not believe we go far enough. It seems to me that we tend to think of organizations simply as environments. Thus, we examine such matters as the effects of differences in the climates of organizations on the types of leadership that are most effective in them and the relationships between various sorts of organizational structures and the need satisfactions of the members of those organizations.

Even dealing with organizations just at this level, taking them solely as social environments, we need more innovation. For example, we ought to be giving much more attention to the sorts of sociopsychological dimensions along which organizations vary. There have been some beginnings, for some of the braver and younger among us have directed their thoughts to the kinds of dimensions that can be used to describe organizations. Nevertheless, we are still at a relatively primitive stage, largely concerning ourselves with variables that simply are descriptive of objective properties such as size and sociological variables such as shape. We need much more creative thinking and much more argument and controversy among ourselves about the pertinent sociopsychological dimensions of organizations.

As we well know, there have been numerous studies of the effects of the organization on the individual, showing various ways in which it modifies his behavior and his thinking, but we have given little or no attention to the effects the individual has on the organization. We should be ex-

ploring such important problems as the kinds of people who can make significant changes in the nature and operation of the organization and the different sorts of changes made by persons of different abilities and personality traits.

Furthermore, I believe that it is legitimate to examine the psychological nature of organizations, taking organizations as wholes. Traditionally, the study of organizations has been the province of the sociologist. Nevertheless, I believe that we, too, can consider business and industrial organizations as individuals, individuals who vary among themselves in a number of different psychological dimensions and who behave in ways that are characteristic of all kinds of individuals.

For example, we can examine how organizations learn. When a factory is charged with turning out some new product, the initial rate of production is low, and apparently as experience is gained, production increases but with diminishing returns, so that a graph of production looks exactly like the traditional learning curve of a single human being. The concurrent changes within the organization can be studied. Sometimes the workers who produce the product discover more effective ways of working. The people who are charged with procurement often find suppliers who can deliver the materiel more quickly and more regularly. More accurate ways of scheduling the flow of different parts of the work may be developed. Industrial engineers have given considerable attention to this matter, but industrial psychologists have almost completely ignored it. Yet, certainly there are a number of psychological problems here, and industrial psychologists should give some attention to them.

It is said that a major problem in studying organizations is the difficulty in securing more than a very few of them that can be considered to be truly comparable. As a consequence, in studies of organizations it would appear that the number of cases must necessarily be quite small. When we study people, however, we certainly do not insist that they be comparable in all manner of characteristics. Indeed, in many situations we actually seek heterogeneity in our subjects so that our findings will be more generalizable, and I see no reason why we cannot argue in just the same way when we study organizations. The use of heterogeneous samples of organizations should make empirical findings more meaningful and reliable.

Nevertheless, it is true that the empirical study of organizations will be more difficult than the empirical study of people. Under the best of cir-

cumstances, it is not easy to obtain a large number of organizations, no matter what kind they are, that can be manipulated and exposed to a variety of specified conditions as we can do with human subjects. Furthermore, social and economic changes are always occurring so that over time we may not have the constant and controlled conditions that are needed. One solution to this problem would be to use simulations of organizations, miniatures, rather than actual business and industrial organizations.

Artificial organizations might be created in the psychological laboratory, organizations that are comprised of relatively few people, perhaps just 10 or 20. For many years, of course, social psychologists have used small groups of people in the laboratory, assigning them various sorts of tasks and systematically varying the conditions under which the groups operate. Many of these studies have been quite fruitful and have provided us with knowledge we would not be able to obtain otherwise. Furthermore, such studies may clarify issues, thus enabling us to do more pertinent field studies. In a similar way, industrial psychologists could assemble groups of people in the laboratory, delegate different roles to the different individuals so that they form the memberships of organizations, assign them some task as a goal of the organizations' activities, and provide them with whatever facilities are necessary. One does occasionally find in the literature reports of research of this sort, but not often, and seldom by industrial psychologists. I believe that the use of miniature models of organizations might be very fruitful. For example, in some exploratory investigations utilizing miniature organizations, I was able to observe the sorts of structural changes that occur in organizations as they develop from infancy to maturity, and thence to senescence.

Another way of simulating organizations is by means of mathematical models. Mathematical models are, of course, common stuff in other social sciences and in other areas of psychology. In economics, for example, we find a variety of mathematical models of the firm. In the areas of psychometrics and learning, mathematical models have been developed that have proven to be quite useful. We industrial psychologists can just as well develop mathematical models of organizations, models that would be useful in showing the effects of various circumstances on specific aspects of the nature and operations of organizations. Let me give an example of the utility of this procedure. A while ago

I worked out a simple mathematical model which enabled me to ascertain the effects of such factors as size and shape of the organization on the quality of men who reach the upper levels of management as a result of regular promotion procedures. Inasmuch as they deal with careers that extend over long periods of years, it is unlikely that matters such as the foregoing can be studied in actual organizations. It is with situations of this sort that mathematical models of organizations, and perhaps even miniature organizations, provide their greatest service.

The Role and Nature of Theory

Now I would like to say a few words about theory and our use of it. I apologize if I appear to be lecturing you on such a basic topic as theory. Nevertheless, it is true that we industrial psychologists almost entirely have been empiricists, and it is only recently that we have generated any real interest in that gossamer we call theory.

We recognize, of course, the value of theory as a means for integrating the many bits and pieces of knowledge we have gained from a diversity of empirical investigations. As a consequence of this integration, theory enables us to view a wide variety of otherwise disconnected facts in a total meaningful whole, and thus it is possible to extrapolate where there are gaps in our knowledge. Furthermore, as we all recognize, theory is very useful in research, for it provides systematic guides to new directions research ought to take and indicates new ideas that should be explored.

Another valuable function that theory performs, and one that we industrial psychologists generally overlook, is as a means for evaluating the significance of empirical findings. Because empirical studies necessarily utilize samples of individuals rather than populations, the findings of a single study are seldom completely trusted, and so, commonly, some statistical test is applied in order to gauge their dependability. Our statistical testing of differences and relationships has become as stylized as the courting dance of the whooping crane and often is just about as awkward.

Inasmuch as theory provides an integration of findings from a diversity of other investigations, if the results of a single investigation are not congruent with an appropriate theory, then certainly there are good grounds for doubting their dependability. Indeed, demonstration of the statistical significance of a set of findings is not enough.

Those findings also ought to fit in with existing theory, or at the very least they should provide a basis for reasonable modifications of current theory or for new theory.

When we develop a theory, we feel committed to defend it to the very end, for we take it as representing the revealed Truth with a capital T. So we bend the large portion of our efforts to finding data that support the theory and explaining away data that are not congruent with it, and consequently we invest too much of ourselves in it.

We take theory as being an approximation of the truth. Our argument is that because our knowledge is incomplete we do not know the precise nature of a particular phenomenon, but only bits and pieces of it. We say that in order for those bits and pieces to be comprehensible we develop a theory that explains them and integrates them into a meaningful whole so that it provides at least a semblance of the truth. As we acquire more and more facts about the phenomenon, we modify our theories or develop new ones to take those facts into account, and thereby come closer and closer to the real truth.

The history of psychology teaches us that seldom are theories disproved by compelling empirical evidence. Rather, theories just fade away because they become less fruitful and less interesting, and so less popular. The work of Wertheimer and Watson did not really completely invalidate the structuralism of Wundt and Titchener. To the generation of psychologists that followed them, the ideas of Wertheimer and Watson were just more exciting, and those of Wundt and Titchener seemed sterile. Whatever happened to Spearman's G? Gone with the wind. Yet, the multiple factor analyses of Thurstone and others did not really disprove Spearman's theoretical position, rather they showed that it is more meaningful and useful to think of human traits as being multidimensional.

Psychological theories wax and wane. They wax as we attempt to overcome the deficiencies of older theory in explaining new facts and seek insights into new problems that now interest us. They wane not so much because they are found to be wrong, but because they do not pertain to the new problems that we, another generation of psychologists, consider to be significant. We ought ever to bear in mind that theories are nothing more or less than conveniences, aids to our understanding the nature of man.

What I am saying is that theories should work for us; we should not work for them. Theories

should be our servants, not our masters. Unfortunately, I fear, the opposite is too often the case.

The Impermanence of Facts

Next I would like to reflect on the survival value of the knowledge we arduously pursue in our so numerous empirical studies and report at such length in the long parade of our voluminous journals. Implicitly or explicitly, our position is that the characteristics of human nature revealed to us from our empirical investigations have the property of enduring truth. We believe that any information we obtain now about human nature was just as true in the past and will be just as true in the future. I wish to suggest to you that this is not necessarily the case. Quite the contrary, what we accept as being facts can by no means be taken to be enduring and established forevermore.

We think of significant fundamental changes in human nature as occurring only over millenia. Thus, we recognize that there are psychological as well as morphological differences between modern men and their arboreal and speluncan ancestors. Nevertheless, is it not possible that changes in the basic character of mental activity can occur over smaller spans of time? Since the turn of the century, has there not been such a variety of most significant social and physical changes in the world that have modified not only the environmental influences on man, but also his patterns of selective breeding? So, is it not possible that in this short span of time there have been significant alterations in the environmental and genetic determiners of human behavior?

Just a few decades ago the son of an immigrant from middle Europe who settled in Chicago invariably married the daughter of another middle-European immigrant, and Back Bay Boston stock maintained itself by careful intermarriage. But the upwardly mobile grandson of those middle-European immigrants attending Harvard Graduate School of Business might well meet and marry a Back Bay Boston lass. It seems highly unlikely that the factor structure of the traits and abilities of the offspring of this marriage, much less their personality dynamics and motivational complex, would be precisely the same as those of their grandparents. Could not the genetic and cultural mix produce something akin to hybrid vigor with rather different psychological laws?

In the last few years we have witnessed the quite sudden appearance of a generation of young people

whose social behavior, attitudes, and values are strikingly different from those of the immediately preceding generation of young people. The change occurred so quickly that we are only beginning to recognize its significance. Surely this surging social movement has brought about basic changes in the psychology of people. The differences between the two generations certainly are more fundamental than just differences in mean scores in hair length, attitudes, motivations, and the like. Is it not possible that culture-loaded and culture-focused instruments such as the F Scale, as well as intelligence tests, do not measure precisely the same qualities in the two generations? Indeed, might it not even be possible that with individuals such as the young people of today, eager to learn so that they can quickly effect social changes, such a basic law as the superiority of distributed over massed practice is reversed so that a quick and concentrated exposure to material results in more rapid learning than exposure to it spread out in time?

While there might be disagreement about the extent to which the fundamental psychological properties of man change over time, there is no question but that the nature of the circumstances in which people work, together with the nature of their work, often change significantly over quite short periods of time. The introduction of stapling machines produced immediate modifications in the work of carpenters and in the particular skills they utilize, and the introduction of computers required executives almost overnight to be able to interpret and utilize great masses of new sorts of information and even to think and to state their problems in different and more precise terms. Consider the great changes in the degree of aggressiveness recently being manifested by those traditionally mild individuals, school teachers, as a result of the new permissive attitude toward unionization and strikes on the part of governmental workers.

A fact about human behavior that is established in a particular situation, with the particular sorts of people who happened to be in it at the time, might well not hold at a future time if the sorts of people attracted to that situation change. There are many obvious circumstances that result in a change in the sorts of people who concentrate in, or are placed in, a particular job. War and economic crises produce such changes, and so do social movements and legislative acts. Unquestionably there are many other factors which we simply do not recognize that cause shifts in the sorts of people who apply for a given job and work at it.

We industrial psychologists have given some attention to changes in the nature of the job and organizational situation with the passage of time, and we have given some, though lesser attention, to the possibility of changes in the sorts of people found in a particular job or organizational situation. But as far as I can see, we have not even recognized the possibility that as time goes by significant modifications in the basic psychological machinery of people may occur.

Fundamental to science is the proposition that facts once established are enduring, for if all were change we would have utter anarchy. Hence, in our training as scientists we were taught to believe that unless the attributes of nature have some permanence, it will be impossible to have any understanding of it. So deeply is this belief ingrained in us that I have felt forced to make as strong a case as possible for impermanence so that you will entertain at least some small possibility that what we think of as established facts are indeed not necessarily enduring. I do not ask you to accept the proposition that all facts change, fade, and pass away as time goes by, but just to admit the possibility that some few might.

I invite you to remember that we industrial psychologists are concerned with men and women who live in a dynamic society, a society that constantly seeks to change their nature, and who are engaged in performing tasks that are always undergoing modifications. As a consequence we ought to expect that what we take to be established facts about workers' behavior are not necessarily true forever.

Individual Differences and Individuality

I come now to the last matter I should like to discuss, individual differences and individuality. A good part of the heritage of industrial psychology lies in differential psychology. The pioneers in industrial psychology, beginning with Münsterberg, all realized that it is necessary to deal with the human problems of business and industry within a framework of individual differences. Unlike some of our colleagues, we industrial psychologists have never regarded the differences among individuals as bothersome "error variance." Rather, we have always considered them as real and important.

Perhaps because industrial psychology also has a heritage in psychometrics, we have generally held that it is more fruitful to think of people as differing among themselves in quantitative rather than

in qualitative ways. For us, people are distributed along continua, not among a series of separate and distinct classes. That is, we hold that the differences among individuals are best considered as being differences in amount, frequency, or degree, and we believe that except for convenience there is nothing to be gained by attempting to separate people into kinds or sorts.

In recent years, our interest in the quantitative differences among people has led us to the examination of moderator variables and their role in contingent relationships. We have considered contingent relationships in connection with a variety of matters such as the validity of tests, leadership, and motivation.

As I am sure you know, a moderator is a variable that monitors the relationship between two other variables. If scores on a variable are related to the degree of relationship between scores on two other variables, then we say it operates as a moderator. Thus, for example, the higher and higher peoples' scores are on the moderator, the higher and higher is the relationship between their scores on two other variables. Other patterns can also occur. The important thing is that for people whose scores fall at different ranges on the moderator, the degree of relationship between their scores on the other two variables is different.

When we examine a variable to see whether or not it moderates the degree of relationship between two other variables, we are likely to analyze our data in a fairly crude fashion. Typically, we divide individuals into a high- and a low-scoring group on the basis of their scores on the presumed moderator and ascertain whether the degree of relationship between scores on the two other variables is the same or different for those two groups.

Perhaps because we have only recently begun to study contingent functions, we like to see the data relative to a moderated relationship presented in a simple manner such as I have just described. However, inasmuch as presentations of this sort are used repeatedly in study after study, I fear that we have come to think of a moderator as a property on which individuals are differentiated into separate and distinct groups, rather than as a continuum on which individuals are distributed all along its extent. Thus, we may say that the findings of a particular study indicate that in organizations that have a tall structure, supervisory success and authoritarian views about leadership are more closely related than they are in organizations that have a flat structure. The moderating variable, organiza-

tional structure, we treat as being qualitative, a variable that classifies organizations by type or kind. In our concern with convenience we overlook the fact that the moderating variable is indeed a continuous one along which organizations vary in accordance with the *degree* to which they are tall or flat.

This view about the nature of moderator variables has been reinforced as we have come to examine as moderators variables that are the classical examples we cite to students as being qualitative variables. Thus, we examine as moderators of the validity of occupational tests, variables such as sex, race, and even "kind of name."

I have no expertise that would permit me to make definitive statements about sex or race as variables. However, I gather from those who are knowledgeable about these two properties that the nature of variation in them is by no means certain, and, indeed, it may well be better to take them as quantitative rather than qualitative variables.

To illustrate the absurdity of dividing people into separate categories in terms of kind of name, currently a popular game in the Far West and Southwest, I give you the case of my youngest granddaughter, Anna Louisa Ghiselli. Just on the basis of her name alone an earnest investigator without any qualms would readily classify her as a child of Latin descent. *Chiaramente questa bambina è una vera latina.* Her ancestry, however, is about one-quarter English, one-quarter Lithuanian, one-quarter Polish, with the remaining quarter being more or less equally divided among German, Portuguese, Italian, and the three major sorts of Swiss. How representative this child of heterogeneous ancestry is of all western hemisphere people, if not indeed of all people of all hemispheres, even those who are called, or call themselves pure stock.

Unless we are concerned with matters such as certain social perceptions, biases, and the like, I can see no value at all in examining the somatic and nominal properties of people as moderators. Indeed, a case could easily be made that when we do use somatic and nominal properties in this manner it is simply because we are intellectually lazy. As psychologists and social scientists we ought to be concentrating our efforts on the examination as moderators of various psychological and social factors. We should be investigating the moderating effects of quantitative variables such as various sorts of cultural deprivations, roles accepted by the individual, the frustrations he develops which re-

sult from aggressions against him, modes of behavior thrust upon him, and the like—solid, directly measured, and significant psychological and social factors.

One of the values of the current social revolution is a reaffirmation that the classes to which people are assigned, classes differentiated on superficial bases such as somatic and nominal characteristics, should play no part whatsoever in making social judgments about people as in personnel selection and evaluation. The position is taken that the sort or kind of person that individual is said to be should be completely ignored, and any differences that are found between so-called "sorts or kinds" of people with respect to employment, job performance, or any social judgment of them should be taken as being purely incidental. If differences between classes are found, those differences are better attributed to more fundamental quantitative psychological and social variables which for one reason or another have some association with those classes.

Indeed, rather than placing importance on the uniqueness of the classes or categories of people, we ought to be focusing our attention on the uniqueness of the individual. Individuality, too, is a real property of people, and yet we have almost completely ignored it. We have not even developed a working definition of individuality, much less ways for measuring or describing it. Is the uniqueness of the person, his individuality, a matter not worth the attention of the industrial psychologist? Should we continue to devote a substantial portion of our attention to highlighting the differences among arbitrary categories of people? A few years ago we happily joined the attack on the stereotype of the organization man, but where is our interest in his opposite, the individualist?

I am certain that systematic investigations of individuality would be most fruitful and would turn up some interesting and surprising findings. For example, in the Italian civil service, an institution noted for its inflexibility and strict adherence to rules and regulation, quite unexpectedly I found that the more individualistic a manager was, the more highly was his work regarded by his superiors.

The intercorrelations among people can be computed from the scores they earn on any set of variables. Invariably these correlations will differ in magnitude so that at one extreme there are some individuals whose intercorrelations are high inasmuch as the order of their scores is very similar, and at the other extreme there are other individuals

whose intercorrelations with other people are low inasmuch as the order of their scores is quite unlike that of any other people. The remaining individuals are distributed between these two extremes. By this simple procedure individuality can be demonstrated and can be taken to be a continuous quantitative variable of exactly the sort we are all used to. There is, then, nothing odd or peculiar about the property of individuality which makes it elusive or especially difficult to deal with.

The many attributes which all men share testify to the oneness of mankind. Human beings are sufficiently similar that we have been able to make many useful and meaningful generalizations about them. However, while quite obviously it is important to study what is common to all men, we must not overlook the richness of what is unique to the individual. And surely there is much more to

be gained from studying the person in the fullness of his individuality than there is from studying what he has in common with others who are placed with him in one or another of a series of contrived categories which are presumed to make qualitative distinctions among people. The point I have been trying to make is certainly not new. It is a cry that echoes down the long halls of the history of man, a cry of the individual for a recognition of his individuality, his uniqueness, and we industrial psychologists have not heeded it. The matter was well phrased some thousands of years ago in the Talmud: "The greatness of God is infinite; for while with one die man impresses many coins and they are all alike, the King of Kings, the Holy One—blessed be He—with one die He impresses the same image on all men, yet not one of them is like his comrades."

Opponent Processes as a Model of Neural Organization

LEO M. HURVICH *University of Pennsylvania*

DOROTHEA JAMESON *University of Pennsylvania*¹

On an occasion such as this one we have an opportunity to pull back from the trees, the underbrush, and thorny bullweed to raise again, in case it has been lost sight of, the central question of visual perception: Why do things look as they do? Because they are what they are? No, because we are what we are.

Some of you will surely recognize the question as one raised precisely in those words by Kurt Koffka (1935). Without getting embroiled in the specifics of the mind-body problem and its many proposed resolutions—it was the subject of a recent major article in *Science* by Globus (1973)—it seems clear to us that the answer to the broad question “Why do things look as they do?” will be given in an informative way only when the principles of neural organization are known. To describe more specifically what we mean by this, we shall ask you to bear with us while we review first the opponent process principles of neural organization in relation to our own earlier work in color and brightness perception, remind you of some of the more recent electrophysiological data that are particularly relevant to these principles, and then discuss briefly the way in which the same principle of spatial neural organization can be shown to account for very different visual phenomena.

The phenomena of visual perception can be approached in a variety of ways, and they are well

summarized in Koch's (1959) volumes on the study of psychology and Floyd Allport's (1955) volume on theories of perception, as well as in the many monographs that explicate a particular theoretical approach. For example, there is Graham's (1965) S-R approach, Gibson's (1966) view of perception as a direct apprehension of the invariants of distal stimulation, Helson's (1964) broadly unifying principle of adaptation level, Hebb's (1949) cell-assembly concept, approaches that emphasize motivational aspects, directive state, the transactional view, and so on. But for a long time, views of visual perception could be roughly divided into either of two camps that might be described as mosaic versus Gestalt, point-for-point image representation versus field representation, or elementistic or wholistic. Moreover, if what is given in the neurophysiology is a response mosaic that reflects each transitory change in the stimulus mosaic, there is obviously much cognitive decoding and resynthesis to be done on route from stimulation to perception. The elementists consequently often stressed the importance of learning as the crucial process whereby the meaningless mosaic of sensory elements could be interpreted as the meaningful forms, outlines, and solid objects of the real visual world. The Gestalt approach to perception, on the other hand, was more compatible with a relatively greater stress on nativism, if nativism here is interpreted as an inherent physiological organization into delimited fields of higher nervous activity that lead directly to figure percepts. So the difference in point of view with respect to elementalism versus Gestalt also carried over into a difference in emphasis with respect to empiricism versus nativism. Conceptual differences of this sort also had their parallels in the rival views of the mechanism of color vision, and these existed long before the formal warfare between the Structuralists and Gestaltists was declared.

¹ This article was delivered as a Distinguished Scientific Contribution Award Address at the annual meeting of the American Psychological Association, Montreal, Canada, August 1973.

The authors are indebted to the National Eye Institute, the National Institutes of Health, and the National Science Foundation for research support. They are also grateful to Ralph M. Evans for his encouragement and administrative support of their early work on problems of color while at the Eastman Kodak Company.

Requests for reprints should be sent to Leo M. Hurvich, or Dorothea Jameson, Department of Psychology, University of Pennsylvania, 3815 Walnut Street, Philadelphia, Pennsylvania 19174.

On the one hand, all of the phenomena of color vision were considered to be interpretive resyntheses of three elementary fundamental sensations that were attributable to three kinds of retinal receptors and their associated nerve fibers; on the other hand, these same phenomena were considered to be attributable to a visual response mechanism whose fundamental properties and principle of organization could be inferred directly from the properties observable in the phenomena themselves.²

Consider, for example, the simplest of afterimage phenomena. Figure 1 shows the bust of a young girl; if you fixate rigorously on a single spot, for instance, the tip of her nose, and then shift fixation to a uniform field, the girl will reappear as an afterimage. You have all seen afterimages of this sort. Elementary texts seem to favor a stimulus that will generate an American flag, or a photograph that will give us W. C. Fields resplendent in top hat. But most of you may not have seen this particular afterimage because the figure comes from the estate of Goethe and was probably painted by him. It appears in a recent American edition of Goethe's monograph on color theory that was translated and edited by Herb Aach (1971) after Mattaei's German edition.

Goethe, as most of you know, was fascinated by visual color phenomena, and although he was mistaken about some of the physical principles involved in producing different kinds of colored stimuli, he had some sharp insights into the principles inherent in the perceptual effects. The negative afterimage he illustrated with this figure suggests, by its very name, the principle of response rebound of opposite quality. When a primary pattern of sustained stimulation has built up one mode of response in the visual system and the stimulus is then suddenly removed, the consequence is a different mode of response, one that is opposite to, or the negative of, the initial response.

Obviously, an opponent physiological rebound is not the only way to account for a negative afterimage that is projected on a uniformly illuminated surface, and elementalists feel quite comfortable with the explanation that the phenomenon results from what is called *local adaptation* or *fatigue* of the retinal receptors.³ If the cone receptors are

Figure 1. Black and white photograph of Goethe's figure for colored afterimage. (For color plate, see Aach, 1971.)

first selectively desensitized by the different wavelengths contained in the different parts of the primary stimulus that is imaged on the retina, then only those receptors that have not been desensitized or bleached can respond to the homogeneous white light of the projection surface, hence the negative afterimage. Other characteristics of afterimage phenomena, which are best summarized as manifesting an oscillatory pattern of opposite effects that tend to damp out in time, make it difficult to avoid postulating an organization of antagonistic neural processes that wax and wane in temporal alternation as the system returns to equilibrium. These oscillatory events tend not to be featured in accounts that emphasize localized receptor bleaching to explain the occurrence of negative afterimages.

The mosaic of receptors hypothesis is still less comfortably accommodated to the phenomena of simultaneous contrast, which demonstrate another principle of neural organization. Just as the negative afterimage can be seen as an instance of *opponent temporal organization*, namely, primary response followed by opposite rebound, simultaneous contrast can be seen as an instance of *opponent spatial organization*, namely, a primary response in one spatial location inducing an opposite response in an adjoining neural region. These spatially opponent effects can, of course, be seen in strictly achromatic patterns, as in Figure 2, where

² A discussion of these views in their historical context can be found in Hurvich (1969).

³ Brown (1965) reviewed such explanations in some detail and also discussed a number of specific photochemical hypotheses that have been advanced to account for afterimage effects.

Figure 2. Achromatic contrast illustration. (Pattern from Albers, 1963, Plate IV-2.)

the gray on the right looks darker than that on the left only because of the luminance difference between the light surround on the right and the darker one on the left.

These spatially opponent effects are equally obvious and important in the organization of the hue-coding system. In the colored original of Figure 3, the two X figures appear in two differently colored surrounds. Although the Xs are spectrally identical retinal stimuli, the different qualities of response induced in the crossed lines by the different surround activities give rise to qualitatively different percepts of two differently colored Xs. An elementalists who is incurably biased against the concept of opponent neural organization to explain spatial contrast has, for his explanation, the choice either of very rapid local adaptation together with eye movements that will cause the surround to desensitize the focal area, or else he must resort to a cognitive unconscious inference hypothesis. In this specific case, it would mean unconsciously assuming that the two sides of the figure are illuminated by lights that are different on the left and on the right. One can usually work out the necessary inferences to come up with a cognitive account of such contrast effects, but it sometimes comes out sounding more like a Watergate cover story than an explanation.

Just to keep the record straight, we have no doubt that there are many situations in which what we see is strongly influenced by what we think is out there, but the universally observed phenomena of simultaneous contrast require something more than that kind of explanation.

If we consider a little more closely the specific character of the oppositions evident in both afterimage and contrast phenomena, they can be itemized very simply: What is light in the primary

image is dark in the afterimage and vice versa, what is blueish in the primary image is yellowish in the afterimage and vice versa, and what is reddish in the primary image is greenish in the afterimage and vice versa. Similarly in the simple contrast situation, the figure in the lighter surround looks darker than the same figure in the darker surround, the figure in the bluer surround looks yellower than the same figure in the yellower surround, and the figure in the redder surround looks more greenish than the one in the greener surround. What we have listed are three pairs of visual qualities that show mutual opposition within each pair: white versus black, blue versus yellow, and red versus green.

Figure 4 describes the appearance of a spectrum with as economical a vocabulary as possible. Starting on the left at the shortest visible wavelengths, around 400 nanometers, we see violet or reddish blue; moving from left to right toward longer wavelengths, the reddishness diminishes until we see simply blue in the vicinity of 475 nanometers; beyond this there is increasing greenness and diminishing blueness and we see simply green near 500 nanometers. Toward longer wavelengths yellowness enters in increasing proportion relative to green, and when we reach approximately 580 nanometers the spectral light appears simply yellow. Orange, or more economically stated, yellow-red, comes in at wavelengths longer than 580 nanometers. The red increases relative to yellow at still longer wavelengths, but spectral light never quite becomes uniquely red out to the long-wave limit of the visible spectrum at about 700 nanometers.

Note that to describe the hues of the spectrum we need the hue names *red*, *yellow*, *green*, and *blue*,

Figure 3. Black and white photograph of colored pattern that illustrates hue contrast. (For color illustration, see Albers, 1963, Plate VI-3.)

but also note that if we are to include all aspects of the spectral light qualities we would, for example, further characterize the yellow near 580 nanometers as more whitish than, say, the very slightly yellowish red at the spectral extreme. The achromatic whitishness or blackishness of each color appearance is a descriptive component just as necessary as the single or binary hue names. Note further that the hue descriptions include the binary pairs red-blue or green-blue but never yellow-blue, also yellow-green or yellow-red but never green-red. Thus, in the simple description of hue qualities we find that yellow and blue are mutually exclusive, as are red and green. This is, of course, true for all colored objects and is not restricted to the spectral light situation. The opponent character evidenced in this property of mutual exclusiveness has the same paired characteristics as the opposition observable in both afterimage and contrast phenomena. What we see does indeed seem to be trying to tell us something about the way the visual nervous system is functionally organized. Moreover, the opponent or mutually exclusive characteristics of the hue qualities themselves suggested the principle of measurement by which the qualitative descriptions that we have just itemized could be subjected to precise psychophysical measurement and expressed as quantitative spectral functions (Jameson & Hurvich, 1955). This psychophysical measurement procedure was a hue cancellation or *bucking* technique. The relative strength of a given hue elicited by spectral stimuli of a series of different wavelengths was estimated by determining the variable energy required at a fixed wavelength that elicited the opposite hue in order for the effects of the two mutually opponent hue processes to precisely cancel each other. For example, we measure how much "yellow" is generated by each of a series of different spectral wavelengths between 500 and 700 nanometers by determining how much energy of a 480-nanometer blue-generating stimulus is necessary to just balance out each of the yellows. The results of this

Figure 4. Description of hues of spectrum with loci of unique hues determined experimentally for one individual. (From Hurvich & Jameson, 1951.)

Figure 5. Psychophysical measures of chromatic and achromatic responses. (From Jameson & Hurvich, 1955.)

experiment for one observer are shown in Figure 5. These are old data which were published in the *Journal of the Optical Society* in 1955, and we show them here simply as basic data for human color vision against which we can compare some of the electrophysiological findings that have emerged from various laboratories, first for fish and then for a variety of animals up through the macaque monkey.

These psychophysical functions not only provide a more precise description of color appearances, but also, since they are quantitative expressions of the three qualitative variables basic to color vision, they permit the derivation of other basic quantitative data of color vision such as the three-variable color-mixture data, wavelength discrimination data, and so on. Such derived functions, compared with independent data measured in various other laboratories, were published many years ago in the *Journal of the Optical Society* (Hurvich & Jameson, 1955) and summarized in the *Psychological Review* (Hurvich & Jameson, 1957).

Figure 6 is a schematic diagram of the conceptual model developed to show how the three paired color variables of the quality-coded neural response system are related to the cone receptors in which the initial spectrally selective light absorption takes place. At the time that this model was developed, the spectral absorptions of the three kinds of cone

Figure 6. Schematic diagram of relations between cone absorptions and opponent response processes.

receptors were not independently known, and their absorption characteristics had to be inferred on the basis of psychophysical data together with specific assumptions about the bleaching characteristics of visual pigments. We now have more information both about bleaching properties and about the spectral absorptions of the cone photopigments (Darnall, 1972). This information comes from a technique known as retinal reflection densitometry (Rushton, 1958; Weale, 1957), which measures light reflected back from the whole retina before and after bleaching, and also from a technique known as microspectrodensitometry, which can measure, at least approximately, the spectral absorptions of isolated, individual retinal cones (Brown & Wald, 1963, 1964; Marks, Dobelle, & MacNichol, 1964). It is on the basis of this independent evidence from the discipline of visual photochemistry that the three kinds of cones, labeled here alpha, beta, and gamma, are specified as containing photopigments whose absorption maxima occur approximately at 450, 530, and 570 nanometers, respectively (Jameson & Hurvich, 1968). Note that in this model there is no suggestion that the receptors themselves provide the color coding. Rather, the color coding is assumed to be associated with the neurophysiological events at the opponent process level (Jameson, 1972). This level is organized, according to the model, in three kinds of paired processes. Within each pair, one response mode is labeled positive and one negative to indicate their opposite physiological characteristics and to accord with their opponent and mutually exclusive perceived characteristics. Which mode of response is

considered positive and which negative is immaterial. The plus and minus signs are used as conventions to indicate oppositeness of response mode and also to express the property that the ultimate net neural response is determined by the algebraic sum of the signed arousal inputs from the excited receptors to which each neural system is functionally related. Thus, if the incident light on a given part of the retina is heavily weighted in short-wave energy, it will be absorbed more strongly by the short-wave alpha receptor than by the beta or gamma receptor, and the signed input from the more strongly excited alpha receptor will be greater than the combined inputs from the less strongly excited beta and gamma receptors which are of opposite sign. Consequently, the net response of the blue-yellow color-coded neural system will be signed as a blue response. If the nature of the light stimulus is changed so that it is now more heavily weighted in energy from the long-wave region of the spectrum, then it will be less strongly absorbed by the alpha receptor than by the beta and gamma receptors, the signed input from the less strongly excited alpha receptor will be less than the combined inputs from the more strongly excited beta and gamma receptors which are of opposite sign, and the net response of the blue-yellow color-coded neural system will now be signed as a yellow response. So the model leads us to expect that, even if we were red-green blind and lacked the red-green opponent response mechanism entirely, we would still retain some spectral color discrimination because the hue-coded response of one sign for short wavelengths would switch to one of the opposite sign for longer wavelengths. Congenital protanopes and deutanopes and normal vision in the retinal periphery are instances of this kind of reduced color vision (Hurvich, 1972, 1973; Moreland, 1972).

How might this bimodality of response be expressed in the electrical responses of individual nerve cells? The first discovery of wavelength-specific neurophysiological response in individual cells of the retina was made by Gunnar Svaetichin (1956) in the isolated fish retina. And this vertebrate, unlike the cat, is known to have good color discrimination. The responses took the form of graded changes in dc potentials that varied in magnitude from one wavelength to the next, and in some cells showed a reversal in polarity of response, from hyperpolarizing potentials at short wavelengths to depolarizing responses at longer wavelengths, or vice versa. Figure 7 shows such records from Svaetichin's work. These results have

been confirmed many times, in the retinas of many species and by different investigators in many different laboratories (Abramov, 1972). The electrical potentials are thought to be responses of the horizontal cells of the retina (Svaetichin & Mac-Nichol, 1958), and they are often referred to as S-potentials in recognition of Svaetichin's early recordings. To illustrate the complexity of the retinal network, Figure 8 shows a diagrammatic cross section from the recent work of Dowling and Boycott (1966) with the rods and cones at the top, horizontal cell sending its processes laterally in the layer between the receptors and the different kinds of bipolar cells, and amacrine cells also sending their processes laterally between the layer of the bipolars and the different types of ganglion cells,

Figure 7. Records showing reversal of polarity of electrical graded potential responses to light stimuli of different wavelengths. (From Svaetichin et al., 1963.)

Figure 8. Summary diagram of the contacts among retinal cells of various types. (R, rod; C, cone; MB, midget bipolar; RB, rod bipolar; FB, flat bipolar; H, horizontal cell; A, amacrine cell; MG, midget ganglion; DG, diffuse ganglion. After Dowling & Boycott, 1966.)

shown at the bottom of the diagram. At the later neural cell level, that of the ganglion cell, the responses are characterized by spike discharges rather than by graded potential changes alone. Instead of electrical polarity reversals exhibited by the graded potentials, the spectrally opponent responses of ganglion cells are exhibited by spiking discharges versus suppression of spiking discharges. For example, when short-wave light stimulates the retina, there may be spiking at the onset of stimulation and suppression of spiking at stimulus offset, whereas at longer wavelengths there may be suppression of spike discharge at stimulus onset followed by a burst of spikes at stimulus offset, the so-called off-discharge. Spectrally opponent responses of this sort have been recorded from ganglion cells of the fish retina and the retinas of other species as well as from the optic nerve, and from both the lateral geniculate and visual cortex of the monkey (DeValois, 1965; Hubel & Wiesel, 1968; Wiesel & Hubel, 1966). Figure 9 shows records of such responses from the work of DeValois and his co-workers. Compare the response to a 440-nanometer light above with the response of the same cell

Figure 9. Series of records showing change in response of a spectrally opponent cell in the macaque LGN. (The cell shows on-responses to short wavelengths [420-480 nanometers] and off-responses to the long wavelengths [500-670 nanometers]. This figure is our tracing of a photographic reproduction from DeValois, 1965.)

to 590 nanometers below. These are records from the lateral geniculate body of the macaque monkey, and in these so-called spectrally opponent cells there is a change from spiking to stimulation at short wavelengths to suppression of spontaneous discharge during stimulation and an after-discharge of spikes for stimuli of longer wavelengths.

If we assume that the coding in a cell of this sort is blueness when the cell fires and yellowness when the cell firing is inhibited by stimulation, then we can relate this pattern directly to the negative afterimage phenomena with which we started this discussion. A short-wave stimulus is imaged on the retina, cells with this particular coding fire, and that firing codes blueness. When the stimulus is removed the cell goes into a silent phase, the coding is the opposite of blueness, namely, yellowness or the afterimage hue. And eventually the cell returns to its spontaneous firing rate again. If the stimulus is of a longer wavelength, the cell is silent while the stimulus persists and fires when it is removed. This is consistent with a yellow primary

hue in this instance followed by the blue afterimage hue when the cell again fires at stimulus off, again with the "firing equals blueness" coding. This is not to say that no bleaching or receptor adaptation or desensitization occurs when an afterimage is developed, but rather to say that the neural organization is such that the opponent activities fundamental to hue perception lead, *sui generis*, to opposite aftereffects.

What of the spatial contrast phenomena that show qualitatively similar effects? If we first put these contrast phenomena into the perspective of the conceptual model, we can then see how the model (Figure 10) relates to the detail seen in electrophysiological studies of individual nerve cells. In looking earlier at the schematic of the conceptual model we considered only what might be called the vertical interrelations, namely, those between the receptor units and the opponent neural response pairs. What the model assumes, in essence, is that specific lateral interconnections exist such that activities aroused in a given paired system, whether in a blue-yellow system, a red-green system, or a white-black system, both influence and are reciprocally influenced by ongoing activities in corresponding adjacent and surrounding neural systems. This influence is assumed in the model to be both mutual and opponent, that is, if, say, blue, or blueness-coded, activity is ongoing in one functional unit of the blue-yellow system, opposite, namely, minus or yellow, activity is induced in adjacent functional units of the same coding. The same mechanism operates, according to the model, in the opponent red-green system, where redness activity:

Figure 10. Schematic diagram of model illustrated in Figure 6 expanded to include representation of reciprocal lateral influences at the opponent process level.

induces greenness activity in neighboring units, and vice versa, and in the opponent white-black system. The achromatic white-black system differs from the hue-coded opponent pairs only with respect to symmetry of arousal. There is no external stimulus to excite blackness directly. In terms of what we called the vertical interrelations, all three types of cone activities arouse activities of common sign in the achromatic system and the code is "whiteness." The oppositely signed blackness response comes about only indirectly as an aftereffect of the direct focal stimulation of the retina, or through the system of laterally induced opponent activities. It is the lateral, opponent, induced activities that are, we believe, responsible for the phenomena of simultaneous contrast. Since the conceptual model has been developed in a quantitative way that also expresses these lateral opponent effects in equation form, we have been able to derive quantitative psychophysical functions to express the amount of hue and brightness contrast effect produced for a variety of stimulus parameters. Again we are referring here to theoretical derivations long published and compared with psychophysical measures from both our own and various other laboratories (Jameson & Hurvich, 1964). There is one set of psychophysical functions contained in that paper that we would like to remind you of because it makes an additional point about the mechanisms of visual perception and a basic principle of neural organization to which we have not yet alluded.

When we think of visual contrast effects, usually the first examples that come to mind are effects that we would have to describe as nonveridical. A gray paper in a light surround tends to look black; a gray paper in a green surround tends to look red, and so on. On the other hand, there are all the phenomena of perceptual constancy which attest to the veridicality of our perceptions of objects despite the changes that their retinal images undergo with changes in illumination, and so on. Is it possible that the same visual mechanism that causes surfaces of *constant* characteristics to appear to *vary* in their perceived color and brightness can also bring about the approximate constancy of object appearances? We believe the answer to be very importantly yes.

Figure 11 shows the extent to which the model predicts that brightness constancy will result by the action of the opponent lateral induction processes that account for simultaneous contrast. The stimulus situation to which the figure refers is a visual pattern consisting of a number of different re-

Figure 11. Theoretical predictions of brightness changes with changes in illumination level of a five-element pattern. (Solid lines, —, indicate photometric predictions; dashed lines, — —, indicate visual predictions based on opponent spatial interaction model [Jameson & Hurvich, 1964].)

flectances that might be described as varying in appearance from near white to very dark gray, and viewed at three different levels of illumination. The amount of light reflected from each part of the pattern increases in the same proportion as the level of illumination is increased, and, if the eye were simply a photometer, then the matching luminance, plotted on the ordinate, would simply increase for each different area in the pattern in direct proportion to the increase in overall illumination, plotted on the abscissa. This photometric prediction is shown by the family of straight lines with a slope of one that are drawn in Figure 11. Each different symbol in the graph refers to an area of different reflectance in the pattern. The equations that embody the opponent spatial interaction concept predict, however, that the changes in apparent brightness will be much less than those that would be recorded by a photometer. The visual predictions are shown by the dashed lines. The pattern as a whole will not show perfect constancy, although a particular area within it may, in this case the area numbered 4 and represented by the Xs in the graph. The departures from constancy are predicted to be such that the pattern will be a little more contrasty, a little sharper, if you will, at the higher levels of illumination. The experimentally measured matching luminances are shown in Figure 12. Here you can see the increase in

Figure 12. Matching luminance data for apparent brightness changes with changes in illumination level of a five-element pattern. (From Jameson & Hurvich, 1964.)

gradient from left to right between the darkest and lightest areas at the different illumination levels.

Painters and artists, of course, do not need a model of the spatial interaction in the visual nervous system to represent this effect in their canvases and drawings. If they want to recreate the impression of bright illumination in a drawing or painting, they do so by manipulating their pigments or shading to increase the contrast from one area to the next. And as we know from the impressionists, they also do not need to be told that the same kinds of effects occur in the opponent hue mechanism: In a painting, increasing the yellow of the fully illuminated area and the blue of the shadowed area is quite effective in representing bright sunlight. But our main point here is that the mechanism of lateral interaction, the same mechanism that causes the changes in appearance that we call contrast, also brings about the relative stability with change in overall illumination that we call constancy, or more correctly in terms of our actual perceptions, approximate constancy.

We wish to consider now another aspect of the spatial neural organization that we believe can account for another set of apparently mutually contradictory phenomena, namely, contrast, on the one hand, and reverse contrast, spreading, or assimilation, on the other. To explore this issue we must look more closely at the detail of the opponent spatial organization as revealed in studies of the electrophysiological responses of individual nerve cells in the retina and other visual centers.

We know that when responses are recorded from ganglion cells in the retina, such a single cell responds not simply to punctiform stimuli located within very tiny areas of the retinal image surface, but rather to stimulation within a relatively large area which is known as the receptive field of the cell. Moreover, the receptive field is characterized as eliciting one type of response in the ganglion cell for stimuli that fall in its center of receptivity, say, "on" responses, and an opposite mode of response, in this case spike inhibition during stimulation with subsequent "off" responses for stimuli that impinge on its peripheral, or surround, area of receptivity (Kuffler, 1953).

We know from the electrophysiological work that at the level of the retina, in fish, the ground squirrel, the cat, and other species, the receptive fields have a typical organization into a roughly circular center with antagonistic annular surround. This type of organization is illustrated in Figure 13. Receptive fields with approximately circular center-surround organizations of this sort can also be located in the higher neural centers, in the lateral geniculate of the cat and the monkey, for example, and we know from the extensive work of DeValois and his associates that many geniculate cells also have spectrally opponent or, apparently, hue-cod-

Figure 13. Receptive field map of ganglion cell in cat retina. (Crosses represent on-discharges [central region], circles represent off-discharges [diagonal hatching, peripheral region]. Both on- and off-discharges occur in intermediate region [horizontal hatching]. From Kuffler, 1953.)

ing properties. Most of DeValois' (1965) records were obtained with large or diffuse light stimuli, and thus provide no information on the receptive field characteristics of the individual geniculate cells. The spatial properties of those monkey geniculate cells whose receptive field properties have been explored with stimuli of appropriate dimensions, for example, by Wiesel and Hubel (1966), seem to fall into a number of different classes whose significance is not directly apparent. Arrangements that would properly code both hue and hue contrast would be center versus surround opposition together with wavelength opposition of reversed sign in both center and surround. Cells of this sort have been detected by Hubel and Wiesel (1968) in the monkey only in the visual cortex where the circular center-surround receptive field organization is not typical but where spatial characteristics that are apparently more highly specialized emerge. Rather than pursuing the neurophysiology of line detectors, curvature detectors, and so on, let us consider a diagrammatic representation that illustrates the essence of the opponent spatial organization that emerges from specific relations assumed between groups of retinal receptor units, on the one hand, and single neural visual cells, on the other. The organization diagrammed in Figure 14 represents a cell that shows a spatially opponent receptive field organization but no wavelength specificity with respect to mode of response. Note that the cell is under the influence of activities engendered when light is incident upon and absorbed by a relatively large number of receptors on the retina, that the inputs from those receptors located in the center of the receptive field of such a cell are associated with one mode of response, and that inputs from other receptors located in the periphery of the cell's receptive field are associated with the opposite mode of response in the cell. If the center is excitatory of spike discharge the periphery is inhibitory, and vice versa. The response profile of such an arrangement is shown in the lower part of the figure and is identical to what Békésy (1968) termed the *neural unit* in dealing with Mach band phenomena. Given stimuli of the appropriate dimensions, such an organization is ideally suited to heighten contrast; thus, a weak light falling on the receptors in the center of the receptive field would cause some firing in such a cell, but a stronger light falling on the receptors in the surround of the receptive field would inhibit or diminish the firing rate of the cell. The net response of the cell would then be equivalent to or even less

Figure 14. Diagrammatic representation of spatially opponent receptive field organization. (See text.)

than what it might be were there no light at all impinging on the receptors centered in its receptive field. So because of this arrangement, a gray spot centered in a light surround would, in terms of its physiological coding, appear darker or blacker than it would if the response depended on the photometric luminance of the gray spot alone. There are, of course, many such cells whose receptive fields on the retinal surface overlap, but a mathematical analysis of the outcome will, under the circumstances described, lead to the same outcome with respect to heightened contrast that we have just described for the single cell that is under the influence of an organized field of receptor inputs.

It should be emphasized here, however, that the outcome of any such spatial arrangement depends very strongly on the dimensions of both the pattern of stimulation on the retina and the receptive field sizes relative to that pattern. Thus, for example, adjacent retinal areas of stronger and less strong illumination that are of very small dimensions such that the adjacent differences in illumination fall not in the center and surround of the receptive field, respectively, but well within, say, the circumscribed central area, will produce no enhancement of re-

Figure 15. Black and white rendering of highly magnified colored detail from Seurat's "Grande Jatte."

sponse differences, but rather they will produce a summated response in the cell. Moreover, an image grain of the sort envisaged here, where the spatial dimensions are very small relative to the dimensions of the receptive fields of the cells responding to the related receptor inputs, will fail to be re-

Figure 16. Black and white rendering of Seurat's "Grande Jatte."

solved at all by such an assembly of visual cells. The perception will be one of uniformity, or of perfect spatial light mixture. Outside of the laboratory, we are probably most aware of such spatial light mixture when we view a pointillist painting at a sufficiently remote distance. On approaching closer to such a painting we begin to resolve the variegated texture of the painted surface, and if we get too close the perception becomes one of an abstract array of differently colored dots or blobs. (Figure 15 is a black and white rendering of a colored detail.) This is a greatly magnified detail of the "Grande Jatte" by Seurat, who, as you know, exploited the spatial light-mixture effect in the development of his very finely structured pointillist technique. A photograph of the full painting is shown in Figure 16.

In view of the crucial nature, with respect to the perceptual outcome, of the dimensions of the receptive fields of visual cells relative to the dimensions of the stimulus pattern imaged on the retina, information about the dimensions of receptive fields of individual cells becomes highly relevant to any conceptual modeling intended to handle contrast and mixture phenomena. From the electrophysiological evidence available for the visual system of the monkey, two general findings about these dimensions can be stated. One is that the diameters of the receptive field centers are smallest near the fovea and tend to increase in size as distance from the fovea increases. The other finding, equally important, is that for any given region of the retina there is a very appreciable spread in the measured diameters of the receptive field centers. Figure 17, from Hubel and Wiesel's work (1960), provides the evidence for both of these statements.

We have seen that, depending on the diameter of the receptive field, for a given pattern of stimulation on the retina, there is a physiological basis for either accentuation of contrast, or mixture and failure of visual resolution. But given the range of receptive field sizes even for cells responding to the same part of the retina, we should anticipate that the responses of some cells would lead to one kind of perception and the responses of other cells would lead to the other. We have, in fact, perceptions that we can readily interpret as the outcome of precisely such a physiological organization, in the visual phenomena called *assimilation*, the Bezold spreading effect, or sometimes, reversed contrast.⁴

⁴ For colored illustrations of this effect, see Evans (1948, Plate XI opposite p. 192).

These are phenomena in which a repetitive pattern is clearly resolved against a differently colored background, and yet the hue or lightness of the pattern seems to be more like the background color, or vice versa, as if the pattern and background were mixing with each other to some extent, rather than contrasting with each other. If the resolution of the pattern as distinct from its background is being carried out by the responses of visual cells with small receptive fields, while at the same time cells with receptive fields too large to provide such resolution are responding to the same parts of the stimulus pattern imaged on the same part of the retina, then the phenomenon of mixture or assimilation of pattern and background at the same time that it is clearly resolved loses its mystery (Jameson & Hurvich, 1972). We shall report on some quantitative aspects of this problem in the near future, but the effect is a large one and easily demonstrated. The pattern shown in Figure 18 is, in the original, printed in three colored inks, namely, a red, a green, and a blue. Separate hues are seen in each of the center bull's-eye and annulus patterns, but they can appear to be mixed in the easily resolved horizontal stripes.

A number of other visual phenomena can also be related to these receptive field size variations. Thomas (1970) considered some of them in a recent review article, and they are unquestionably at the base of the many effects that can be shown to be frequency specific (Blakemore & Campbell, 1969), since spatial frequency is a special case of variation in image size. Moreover, some organization of cells with common spatial properties must be assumed if we are to explain the various specific adaptation phenomena that are variants of the McCollough effect, which McCollough (1965) originally demonstrated as a specificity that conjoined hue, size, and orientation. The way in which such highly specific cellular receptive field organizations can arise at the cortical level through inputs of systems of cells with shared hue and dimensional properties would require a whole additional exposition. Hubel and Wiesel (1965) worked out a detailed schema for achromatic cells for the cat cortex, and a similar scheme works out for the human or monkey cortex if we add the necessary additional variable of hue specialization with its bimodal opponent properties.

One of the general points that we should like to emphasize about the visual system is that the system is organized by means of opponent processes to yield a general tendency toward reestablishing equilibrium whenever the balance of the system is

Figure 17. Diameters of receptive field centers in degrees (logarithmic scale), plotted against distance in degrees of each field from the fovea. (X, on-center units; Δ , off-center units. From Hubel & Wiesel, 1960.)

disturbed by stimulation. Thus, the light stimulation that is followed by a back reaction, which can be observed phenomenally in afterimages, is more correctly understood as stimulation of one state, which state itself acts as an internal stimulus for the arousal of the opposite neural process. If the stimulation were to continue unchanged in time, the two opponent processes would cancel each other in time, and there would be no phenomenal experience except the negative one of disappearance—fixed images disappear. So the opponent neural organization is an equilibrium-seeking device, but this equilibrium seeking is itself thwarted by an opponent system of another sort, namely, the efferent system to the muscles that under normal conditions keeps the eyes in motion so that the retinal image cannot be still even in a motionless external

Figure 18. Black and white photograph of colored pattern that shows both contrast and assimilation. (See text. Colored original by David L. Burke Design Corporation for Scott, Foresman Publishers.)

environment. Similarly, the opponent center-surround organization of the receptive fields of nerve cells that serve so well to accentuate border contrast, produce Mach bands, and so on, are ideally organized to turn off when the retina is presented with a spatially homogeneous field of stimulation, or Ganzfeld. A visual field that contains no spatial gradients contains no spatial information, and hence nothing is lost by an opponent organization of the neural system that gives a net response of zero when the information content is zero, even though, in terms of light quanta, there may be an appreciable amount of stimulus energy flooding the retina.

It is the equilibrating effect of the opponent processes during continued stimulation and the release of the strong back-reaction when the primary stimulus is suddenly removed that Solomon has found especially enlightening in relation to a totally different class of phenomena. What Solomon and Corbit (1973) were concerned to understand were sequences of emotional states, or animal behaviors that imply emotional states, and they found the opponent process concept a fruitful one to pursue in their attempts to relate a variety of behaviors associated with learning, habituation, and addiction. As one example from the animal learning area, dogs given shock react with a set of responses that typically suggest a state of unpleasant emotional arousal. When shock terminates, another set of responses occurs that imply what might be called pleasurable relief or perhaps even joy. With longer periods of exposure to the shock stimulus, the intensity of the initial, unpleasant-affect behavior diminishes, but what might be called the relief syndrome after shock termination shows no comparable decrement in the intensity of its expression. The failure of the primary response and the after-effects to build in intensity or wane together seems paradoxical at first, but it follows naturally if, by analogy with the visual situation, what is happening during the primary stimulation is (a) a direct response appropriate to the direct stimulus and (b) an opponent neural response that builds in time in such a way as to restore the system to a new equilibrated state. In the visual situation the image fades more or less during continued exposure of the eye, but the afterimage seen when the eye is relieved from the continued stimulation increases in strength with the duration of the primary stimulus, just as the dog who whimpers less with continued exposure to shock still wags his tail at least as vigorously when the noxious stimulation is termi-

nated. For many other examples, and the potential application of the opponent process concept to the problem of drug addiction, we can better refer you to Solomon and Corbit (1973).

The opponent principle can be seen as operating not only as between states of nervous activity and between inputs at the cellular receptive field level, but also as between areas of the brain that seem to be mutually and reciprocally related in the control of specific behavior. Sprague (1966) discovered such an organization in the control of visually guided behavior in the cat. In this instance, removal of a large area of visual cortex on one side of the brain resulted in functional blindness in a large part of the animal's visual field. Additional removal of more brain tissue from the superior colliculus on the opposite side of the brain had the surprising result, not of increasing the visual disability, but rather of restoring to a large extent the functional efficacy of the presumably blind part of the visual field. And it is not hard to find the general principle of balanced control also operating in the behavior of human patients who have suffered serious brain damage. A case that we personally observed this past spring gave evidence of an aphasic anomia—loss of ability to produce names of familiar objects and persons—after severe temporal lobe damage. During the acute recovery stage, the patient talked volubly and excessively, and the anomia was extreme. As time passed and the spontaneous verbal speech flow diminished, the anomia also began to show marked improvement. As Oscar Marin, the clinical neurologist in the case pointed out to us, it was as if the recovery of an inhibitory control in the regulation of the speech behavior was necessary to restore the quality of the output and to release the verbal retrieval processes once again.

By citing these few examples from the recent literature and from our own recent observations, we hope we have not given the impression that we believe the principle of opponent processes to be a newly discovered one in behavior or in physiology. We are, of course, well aware of the history of this general concept in human thought, whether in Hegelian philosophy, the dialectical materialism of Marx and Engels, Pavlovian excitation and inhibition, Sherrington's reflex control of muscle antagonists, matter and antimatter in contemporary physics, or the fundamental Yin and Yang principle that permeates the Oriental point of view. A general principle, universally applied, easily becomes a useless cliché. But our point here is that

the opponent process concept, used as a guiding principle in analyzing specific aspects of particular psychological phenomena, may continue to provide the most useful key to the behavior of the nervous system, as it has already proved to do in the analysis of particular visual phenomena.

Editorship Nomination

The APA Publications and Communications Board invites nominations for the editorship of the *Journal of Counseling Psychology* for the term running 1976 through 1981. In order to provide a year of overlap with incumbent Ralph Berdie in 1975, the Board will appoint an editor-elect this year. Members wishing to suggest candidates should prepare a brief statement of one page or less in support of each nomination and mail no later than March 1, 1974, to Anita DeVivo, Executive Editor, APA Journals, 1200 Seventeenth Street, N.W., Washington, D.C. 20036.

The Semantics of Children's Language

PATRICK SUPPES *Stanford University*¹

Interest in language, especially that of children, has become a central concern of contemporary psychology. This interest is somewhat surprising, because everyone recognizes the enormous complexity of language use and language development in the child. In spite of a widespread recognition that there is little hope of having a complete theory of these matters at any time in the near future, a general air of activity and in some cases of optimism prevails about the progress being made. For example, it is now possible to cite a fairly large number of references in the literature on almost any aspect of language development in the child, ranging from phonology to semantic comprehension, with probably the largest number of studies being on the syntactical or grammatical development of children's language. It is surely in this area that the most progress has been made over the past decade or decade and a half.

I have been involved in several such grammatical studies myself (Suppes, 1970; Suppes, Smith, & Léveillé, 1972), and I believe in the intrinsic merit of the diversified work that is going on all over the world. On the other hand, I do feel that too great an emphasis has been placed on grammar or syntax, and too little on semantics. I want to try to help redress the balance by making the case for an intensive study of the semantics of children's speech. I shall be especially concerned to argue that there are as many conceptual and technical tools available for semantical analysis as there are

for syntactical analysis, but as yet these tools are less familiar to psycholinguists and to psychologists in general than is the concept of a generative grammar. Moreover, psychologists have developed a habit of listening to the latest word from linguists on syntactical matters, and to some extent this has transferred to semantics. Part of my thesis is that while linguists have had little of interest to say about semantics, there is a deep and conceptually rich tradition in logic and philosophy that can be used for the semantical analysis of children's speech and that can provide a body of methods and concepts appropriate to the task. It is not my objective to be controversial and dialectical in this lecture, but I want to emphasize from the beginning my conviction that when it comes to semantical matters, the tradition of model-theoretic semantics that originated with Frege (1879) in the nineteenth century is the serious intellectual tradition of semantical analysis, and the recent offshoots by linguists, to a large extent conceived in ignorance of this long tradition, have little to offer in comparison.

Logical Tradition

The tradition I identify as beginning with Frege—although it has an informal history that runs back at least to Aristotle—is concerned with providing a precise and explicit analysis of the meaning of an utterance. This is not the place to give a history of these developments, but I do want to sketch the central concepts that are particularly relevant to the analysis of children's language. It came to be recognized fairly early that one way to analyze the meaning of an utterance is to state under what conditions the utterance is satisfied. In the case of declarative sentences, this amounts to giving truth conditions; in the case of questions, conditions on a correct answer; and in the case of commands, conditions on a response that satisfies the command.

Perhaps the most important step after Frege was the explicit analysis of the concept of truth by Tarski (1935) in his celebrated monograph. Tar-

¹ This article was delivered as a Distinguished Scientific Contribution Award address presented at the meeting of the American Psychological Association, Montreal, Canada, August 1973.

The research reported here draws upon collaborative work with a number of younger associates, especially Elizabeth M. Gammon, Madeleine Léveillé, Freeman Rawson, Robert L. Smith, Jr., and Peter Wu. Figure 1. Semantic tree for the English noun phrase *black cats*.

ski's analysis of the concept of truth is restricted to formal languages, and much of the development of semantics in logic and philosophy since the 1930s has been concerned with formal languages. No doubt the preponderance of emphasis on formal languages has put off deeper perusal of these matters by psycholinguists who might otherwise be attracted to the theoretical developments. What has come to be called the theory of models in logic, which is really the semantical theory of formal languages, has been relatively inaccessible to outsiders until fairly recently.

As I have already indicated, it is my contention that the concepts developed in this logical tradition are of central relevance to the semantics of children's language. I want to sketch why I think this is so, but also to emphasize that I do not claim that all the intellectual problems that must be faced in giving an adequate theory of the semantics of children's language can be solved by any simple and direct application of the concepts taken from the logical theory of models. I shall have more to say about this later.

The basic semantical notion is that of a sentence or a collection of sentences being satisfied in a model. The intuitive idea of such satisfaction is close to the intuitive concept of truth.

Thus, when Nina (one of the children I shall be quoting extensively in this article) says "Bring me some more candy canes," the semantics of satisfaction of that command is, it seems to me, as straightforward as satisfaction of the simple mathematical command "Add 5 and 7." We all have a clear in-

tuitive understanding in both cases of what satisfaction of the command is and what the appropriate state of affairs would be in which either command would make sense with its satisfaction being describable in relatively simple terms.

To make these intuitions explicit is much easier in the case of elementary formal languages. Their syntax is restricted to sentential connectives, predicates, variables, the universal and existential quantifiers, and parentheses for punctuation. A model for a sentence of such an elementary formal language consists just of a nonempty domain, a subset of that domain for each one-place predicate, a binary relation for each two-place predicate, and so forth. A simple, but explicit, formal definition of what it means for a sentence to be satisfied in such a model is then easy to give.

Once a concept of a model is introduced for an elementary formal language, the most important semantical relation between sentences, that of logical consequence, is easily defined. One sentence of the language is a logical consequence of a second just when the first sentence is satisfied in any model in which the second is satisfied.

Direct application of these ideas to a child's language encounters at least three sorts of difficulties. First, the syntax of the child's language is more complicated than that of elementary formal languages, even in the case of a child between the age of two and three years. Second, the idea of considering *any* model of a child's utterance seems on occasion too broad and leads to a notion of consequence that seems too general. Third, the sentences of an elementary formal language are self-contained in their meaning relative to a model that can be easily described. In the case of much of a child's speech there is a vagueness of context and at the same time an apparent high dependency on context that is not easily dealt with by any explicit notion of model. I want to say something about each of these difficulties in turn.

Semantics of Context-Free Grammars

The approach to the first problem of syntax is to restrict initial analysis to that part of the child's language for which a context-free grammar can be written. The semantics of such context-free languages or context-free fragments then consists essentially of two parts. The first part is the assignment of a denotation to individual words or phrases occurring in the child's speech. In many instances, this assignment of denotation would of

course vary from one context of use to another, but this variation merely corresponds to using different models on different occasions. Thus, when Nina says "Get big ball," we assign the denotation of a certain two-place relation to *get*, we assign the set of balls in the immediate environment as the denotation of the word *ball*, and we assign a denotation to the adjective *big* that is not simply the set of big things in the environment, but something more complicated that I shall discuss later in a more detailed consideration of adjectives.

The second part of the semantics is to provide rules for putting the individual denotations together in a way that fits hand and glove with the syntactic structure of the utterance by assigning a semantic function for combining denotations to each production rule of the grammar. This may sound somewhat abstract and complex, but the intuitive idea is simple, as may be illustrated in some examples drawn from a second corpus, a group of six-year-old black children talking to each other (these children were born and live in Southern California). One of the children said "Black cats could climb up a ladder." Let us look at the subject noun phrase *black cats*. Our grammar for noun phrases contains the production rule $NP \rightarrow Adj + N$. As shown in the tree in Figure 1, the semantic rule attached to the grammatical rule is simply that of intersection for this simple noun phrase. On the left-hand side of each node we show either a terminal word or a grammatical category, and to the right of the colon in each node, the denotation of that node. Thus, in the present case the denotation

Figure 3. Semantic tree for the Mandarin noun phrase *hong2 mao2yi1*.

of *black* is the set B of black things, and the denotation of *cats* is the set C of cats. Using the semantic rule of intersection, we see that the denotation of NP as shown in the tree is simply $B \cap C$.

A French sample of a similar sort, taken from the corpus of Philippe, a young Parisian child, indicates that the semantic tree for a noun phrase looks very similar, even when the adjective follows the noun, due to the fact that intersection of sets is commutative (see Figure 2). In the simple case under consideration, similar semantic trees can be found in languages quite different from English. Here is an example drawn from the spoken speech of Lingling, a two-year-old child whose language is Mandarin and who lives in Taiwan. The semantic tree for *hong2 mao2yi1* (red sweater) is shown in Figure 3.²

The three examples I have given are exceedingly simple. It is no triumph for any theory to be able to give an analysis of them. On the other hand, it is not appropriate here to undertake a full-scale systematic analysis of the speech of any of the children referred to. Extensive technical reports already exist for several of the corpora, and some of the analysis is so detailed and massive that I wonder if the reports will have any readers besides the authors themselves (Smith, 1972; Suppes, 1971; Suppes & Gammon, 1973; Suppes, Smith, & Léveillé, 1972).

² Examples drawn from the Lingling corpus are written in pinjin notation for Mandarin with tones indicated by the numerals 1-4 to make possible linear processing of computer input and output.

Figure 2. Semantic tree for the French noun phrase *crayon rouge*.

To provide illustrations that I think are suggestive of the direction taken by the full-scale analysis, I would like to consider four topics: the definite article, adjectives, quantifiers, and the expression of propositional attitudes in children's speech.

THE DEFINITE ARTICLE

In English the definite article is not used at the very beginning of connected speech by young children, but it does appear early. In the case of Nina, shortly after she was two years old frequent uses are found: *the little boat, the little baby, I want the next page, I don't want the finger, I want the lion.*

The use of the definite article is even more common in spoken French at the age of two or shortly thereafter. Here are some of Philippe's examples: *pas chercher les voitures, dans la main, tombe le nounou, la voiture, va chercher l'avion, tombé sur la tête, de l'eau, plein sur la cuisse, mangé le yaourt, le train, le métro, la valise, les chaussons là, chercher les livres, tour de la musique sur le noteur.*

Because there is no exact equivalent of the definite article in spoken Mandarin, I shall only consider the semantics of English and French. This does not mean that there is no way of giving definite descriptions in Chinese; rather it means that different semantical and syntactical methods are used.

There is a familiar story in logic and philosophy about the analysis of definite descriptions and the introduction into formal logic of an explicit notation for the definite description operator. One of the classics of twentieth-century philosophy is Bertrand Russell's (1903) famous article on definite descriptions in which he shows how such descriptions can be eliminated in favor of more primitive logical concepts. His classic example is "The present king of France is bald." For analyzing children's speech or the informal talk of adults, the kind of analysis provided by Russell and the subsequent logical literature on definite descriptions does not seem to provide exactly the right approach because the objective of the kind of analysis that deals directly with the spoken language is, as I have indicated, to provide a semantics that fits *Sem-I* and *Sem-II* with the syntax.

For this purpose, I have found that in many cases, but perhaps not all, it is useful to let the definite article *the* in English (and usually the corresponding definite article in French, for example, denote a set C that is the union of the set of ob-

jects in the periclitical *surround* (with the set of objects denoted by phrases in immediately preceding sentences in the conversation, and in some cases, also the set of objects denoted by images or symbolic storage in long term memory). Thus, when Nina said "I want the lion," the set C denoted by *the* is intersected with the set of lions both real and toy, and if everything is in good order, the set intersection consists of a unique object. The set C as I have described it might in some cases be too large and thus the intersection would be too large. One device by which we can narrow the set C is to use a sequence of sets C_i with each element of the sequence being contained in the preceding member. The C_i that is appropriate in a given case is the first one that leads to a unique object when intersected with the set denoted by the remainder of the noun phrase. Without entering into technical details, I do want to remark that in the case of the definite article the correct semantic function for the production rule is not simply intersection but intersection only in the case when everything is normal. When it is not, some Fregean or Russellian device is used. Obviously also the analysis must change when the definite article is used with a plural noun phrase, as when Nina says "I want the big boxes." In this case, the semantic function places a different cardinality requirement. Rather than a unique object in the intersection there must be at least two objects for the normal meaning to go through.

Whether the explicit decision is taken to let the definite description denote when the proper number of objects is not found in the intersection is really a technical decision and not an important conceptual one. One alternative is to treat the phrase as meaningless and nondenoting, and another is to introduce some arbitrary abstract object as Frege suggested. What is interesting is that the decision here is about as arbitrary and conventional as it is in the case of highly formalized languages, for example, as in a formalized language for axiomatic set theory.

To give you a crude idea of how the set C works in the analysis of the spoken language of the Southern California black children I mentioned earlier, Elizabeth Gammon and I looked at the 400 noun phrases in the corpus (Chapman & Gammon, 1973). It was our approximate judgment after we examined the 263 uses of the definite article that in 126 cases the set C could be restricted to the periclitical *surround*. In 96 cases the set C could be restricted to objects denoted in immediately pre-

setting sentences, and in 25 cases familiar objects like the moon, whose image or symbolic description was stored in long term memory, seemed appropriate. In 12 cases the object referred to seemed to be in the mind of the speaker alone, and there was no easy extraction of the appropriate set C.

To give a sense of the frequency of occurrence of the definite article in the case of Nina, her speech recorded periodically from the age of 23 months to 39 months, with a corpus consisting of 102,240 tokens, contains 4,144 occurrences of *the*. Thus a requirement of any systematic semantics of Nina's speech is to provide an analysis of the definite article.

In the case of Philippe's spoken French, running from the age of 25 months to 39 months, there are 56,982 tokens. *Le* occurs 1,641 times, *la*, 1,457; *l'*, 610; and *les*, 777 times.

Of course, the semantics of the demonstrative adjectives is very close to the semantics of the definite article. I shall not consider the ways in which we think they should be given a somewhat different semantics from that of the definite article to indicate continuing focus (*this* in English) or change of focus (*that*). In the case of Nina, there are 2,075 occurrences of *that*, 1,497 occurrences of *this*, 246 occurrences of *there*, and 341 occurrences of *there*.

SEMANTICS OF ADJECTIVES

I turn now to some semantic subtleties involved in the use of adjectives. Native speakers of English will say almost without exception big red book, little blue box, and so forth, but not red big box or blue little box. There is a good semantic explanation of this fixed order, and the order is found almost without error in young children's speech from the very beginning of the production of phrases that use an adjective of size as well as an adjective of color or some other adjective of simple classification. In the case of Nina, there are 170 occurrences of *big* and 674 occurrences of *little*. Here are all the instances in which either *big* or *little* is combined with an adjective of classification (there are other instances of intensifiers, but for example, great big, that I shall not examine). *Big black*; and a *big white one*, and *there a big white one*; *big black seal*, *big dirty on her big mouth*, *big tiny mouth*; *yeah my big blue dog*, *I want the little tiny baby*, *little tiny flower*, *the little tiny one*; and *my little tall monkey*, *I got this poor little blanket* (the only case of reversal of the fixed order mentioned above), *I want my little white*

blanket, *little green to Mr. Mr. Wood's little green chair*, *my little white house*, *where's the little tiny one?*; *where's the more little green chair?*, *where's the little green chair fall down?*, *yeah that's my little washing machine like you have a washing machine downstairs*.

In the case of standard spoken French, the primary order is the adjective of size preceding the noun, which is followed by the adjective of classification. Here are a few samples from Philippe's speech: *cherches deux petites cabanes bleues*, *où il est le petit filé rouge?*, *une petite vitre carrée*, *une petite fenêtre ronde*, *après il a mangé le petit chapeau rouge*; *et un petit nez noir*; *le petit bonhomme blanc*; *les petits bouts ronds là*; *le petit bonhomme blanc où il est*, *la voiture elle fait tomber le petite machine verte*, *c'est quoi ces petits bouts ronds?*, *c'est quoi ces petits bouts ronds là?*, *tu vois les petits points rouges?*, *tu vois un petit rayon rouge?* (*pour voir*), *mais je prépare des petites cabanes bleues*.

In the case of Lingling's Mandarin, the word order is similar to that of English, that is, the adjective of size or of some other characteristic of variable intensity precedes the simple adjective of classification. Again as in the case of Philippe, I have not attempted to present a full listing, but only to give some samples. *xiǎo chéng, xiǎo, xiǎo* (small real prince), *xiǎo chéng, xiǎo chéng* (small real rat), *xiǎo, xiǎo, xiǎo* (small short man), *xiǎo, xiǎo, xiǎo* (small white rabbit), *dōu dōu dōu* (big white goose), *dōu yǎo lóng* (big wild cat), *dōu dōu jī* (big female chicken).

The same regularity is exhibited almost without exception in the speech of the youngest children from Southern California. What is imperative in these last sample corpora is the uniformity with which the standard usage is followed even in quite early stages of a child's speech. It might be argued that the problem is unique in French. Still, important is the way in which Philippe uniformly gives *grand* or *petit* before the noun and adjectives of color like *rouge* or *bleu* after the noun.

Let me illustrate with an artificial example. *Chien* I think is a reasonable representation of the underlying semantics, and why we place the adjective of variable intensity prior to the adjective of classification. In Figure 4 we see a set of data in the top row marked 1, 2, 3, 4, 5, 6, 7, 8, 9, 10. If we add the derivation of *big* and *small* we get the next row, the single large group. If we add the derivation of the end *big* and *small* we get a second group, the first group with *big* and *small* added. If we add the derivation of the end *big* and *small* we get a third group, the first group with *big* and *small* added. If we add the derivation of the end *big* and *small* we get a fourth group, the first group with *big* and *small* added. If we add the derivation of the end *big* and *small* we get a fifth group, the first group with *big* and *small* added. If we add the derivation of the end *big* and *small* we get a sixth group, the first group with *big* and *small* added. If we add the derivation of the end *big* and *small* we get a seventh group, the first group with *big* and *small* added. If we add the derivation of the end *big* and *small* we get an eighth group, the first group with *big* and *small* added. If we add the derivation of the end *big* and *small* we get a ninth group, the first group with *big* and *small* added. If we add the derivation of the end *big* and *small* we get a tenth group, the first group with *big* and *small* added.

SET OF DOTS

BIG DOT

THE RED BIG DOT

RED DOT

THE BIG RED DOT

Figure 4. Denotations of various noun phrases illustrating the order of modifying adjectives.

which is green, and then ask for red, but there is no big dot that is red.

On the other hand, if we start the other way and ask for the denotation of *red dot*, we get the two red dots. Then if we ask for the big red dot we apply the intensive adjective *big* and select the larger of the red dots.

The idea behind this can be expressed in abstract terms in the following way: First, we intersect the set denoted by the noun with the set denoted by the adjective of classification. We order this set according to the ordering relation denoted by the adjective of intensity, in the present case, the adjective *big*. If we are talking about the upper end of the ordering, we then select as the denotation of the noun phrase the single largest object or something close to the single largest object, for example, a small subset. It is easy to make all this quite precise in terms of a few mathematical symbols, but that is not my objective here.

For those who are somewhat uneasy about the absolute definiteness of my example in terms of dots, they can substitute *biggest* for *big* and obtain a quite unambiguous analysis. Thus, in the second line we talk about the *biggest dot*, in the third line the *red biggest dot*, which is most unusual English, and so forth. I should mention that I have not analyzed the example in terms of the completely semantically unambiguous superlative, because the use of the superlative in children's language is relatively rare. As already mentioned, there are 370 occurrences of *big* in the Nina corpus and 674 occurrences of *little*. In contrast, there are just five occurrences of the comparative

bigger and three of the superlative *biggest*, and just three of *littler*, none of *littlest*, none of *smaller*, and one of *smallest*. When I have spoken of the ambiguity of *big* I mean that exactly what initial segment of the objects ordered by size is selected as the denotation will vary from one circumstance to another. I do think the analysis in the present case that sharply differentiates the semantic function associated with an adjective like *red* as opposed to an adjective like *big* is in first approximation correct and represents a useful insight into the subtleties of the use of adjectives in English. Let me mention also that there are cases, and they are proper cases, of usage in English in which the order is reversed. For instance, if someone is looking at two large chairs among a collection of chairs and one of them is green and one of them is red, it is appropriate to say, Give me the green big chair.

Further complex things about the semantics of adjectives are encountered in children's speech. For example, there are 260 occurrences of *another* in the Nina corpus and 227 occurrences of *other*. The semantics of these two adjectives is obviously not in any sense the simple intersection function. Cardinal numbers and their different usages and positions raise additional problems, but here there is a longer tradition and therefore a more straightforward sense of what is correct.

As fascinating as these further details about adjectives can be, in order to give a survey I move on to the special case of quantifiers, which can be treated as adjectives, but in my own analysis should not be.

QUANTIFIERS

To keep the story simple I restrict myself only to the classical quantifiers *all* and *some*. And here is Nina at her classical best: *all colors, all of they gonna go in here; all the animals did; all the ducklings going to the California; all these and these children are gonna eat; mommy I need all the pieces cut; and I got some lambs; and I want some people; and I made some pancakes; and some snakes were wrapped up together.*

It is my contention that the meaning of *some* and *all* in these examples from Nina's speech is almost without change the same as in classical mathematical language when we say *All even numbers are divisible by two* or *Some prime numbers are twin primes*, or as another parallel from the classical examples of Aristotle: *All men are mortal*,

some men are tall. At the age of 30 months Nina was handling quantifiers with beautiful precision. Compare this fact. It was not until 1879, upon the publication of Frege's *Begriffsschrift*, that an explicit theory of quantifiers was formulated. Today, the theory of quantification, in the sense of the theory of the universal and existential quantifiers, is taken to be at the heart of general logic. I have even heard one paper by a philosopher in which the theory of predication and quantifiers was taken to be the most distinguishing characteristic of human as opposed to nonhuman, animal thinking. I am pleased to report that Nina and other children like her seem to have these matters under good control at a very early age.

There are two aspects of Nina's use of quantifiers that I think are representative of the use of a large number of children, but which receive no treatment in Aristotle and very little in the logical tradition from Frege onward.

The first is that both the existential and universal quantifiers, but especially the existential quantifier, occur more in object position than in subject position. The object position for quantifiers is especially natural in stating commands or expressing wants or needs, and it is exactly the logic of such statements that has been ignored until recently in the development of explicit logical theory. Three examples that have not yet been cited, but that would be typical of Nina's use of the existential quantifier in object position would be these: *I want some diaper pins; I will get some blocks; I want some more toys.*

The second point is that the universal quantifier is so often used in conjunction with the definite article. There is a kind of concreteness and contextualism about this, which is especially reinforced by the earlier analysis given of the definite article, that makes this the natural way to talk, rather than using the universal quantifier in unrestricted form. Thus when Nina says *all the animals did*, she is referring to the toy animals in the immediate context, and the definite article *the* makes that clear. The same kind of remark applies to her statement about all the ducklings. An example in which she may use a demonstrative adjective rather than the definite article is this: *All these clothes are getting off.* The force of the definite article or the demonstrative adjective is to restrict the universal quantification to the contextual set at hand, and this is where a restriction properly belongs. Aristotle's or Frege's unrestricted universal quantifier can be defended in terms of logical sim-

licity, but for working purposes the canonical use of quantifiers is *all the xs*, not *all xs*. This has been too little remarked upon in logical theory, but is evident enough in Nina's speech.

One final remark is needed on Nina's use of *all* and *some*. I have not covered the many different uses of these words as adverbs or parts of adverbial phrases, but in relative frequency these uses are as common as the direct use as quantifiers. In almost all cases, however, the semantical function of the words is similar to their straight function as quantifiers. I have deliberately avoided defining explicitly the semantic functions associated with the production rules by which quantifiers are introduced, not because I think the subject is unmanageable, but because the explicit treatment is rather technical. At least I do not yet understand how to present it in a way that is not technical. The semantics is simplest in my judgment when quantifiers enter at a high level in the derivation tree, and not at the level of adjectives that are part of noun phrases.

PROPOSITIONAL ATTITUDES

There is an important and fundamental distinction in logic that is not needed for the classical development of the foundations of mathematics, but that is essential for obvious distinctions in the use of ordinary language. This is the distinction between language that is purely extensional and language that is intensional. The most obvious way in which language is used intensionally is in the expression of necessity, possibility, or propositional attitudes. Examples of the expression of propositional attitudes are statements about beliefs, needs, wants, expectations, or fears. They are expressed by a wide variety of verbs in every natural language.

Because of the importance and interest in these matters in any complete analysis of the semantics of natural language, let me give one example that is classical in the philosophical literature, but is not directly pertinent to Nina's speech or that of other children her age. The example concerns the non-truth-functional or nonextensional character of belief statements. Thus, from knowing that the statement *The earth is flat* is false, we can infer neither the truth nor falsity of the statement *John Jones believes that the earth is flat*. Similarly, from the truth of the statement *The sun is larger than the earth* we can infer neither the truth nor the falsity of the statement *Aristotle believed that*

the sun was larger than the earth. I have no direct analogues to these examples in the speech of Nina, because no form of the verb *believe* or the noun *belief* occurs in our extensive sample of her speech. As you would also expect, there are no instances of statements of possibility or necessity. There are, however, numerous instances of the expression of propositional attitudes, especially expressions of wants or needs, and there are many expressions of *because* or *-cause*.

The case of the various forms of *want*, for example, *wanna*, is striking. Of the large corpus of over 100,000 words, somewhat over 1% are occurrences of some form of *want* (*want*, 883; *wanna*, 359; *wants*, 60; *wanted*, 6).

One useful distinction in the use of terms or noun phrases in the expression of propositional attitudes occurs already in Nina's speech. This is the distinction between attributive and referential use of terms, a distinction already recognized by medieval logicians who characterized the referential reading as giving us a statement *de re* as opposed to the attributive reading which yields a statement *de dicto*. Both attributive and referential uses occur in the Nina corpus. Here are some examples of attributive uses: *He don't want a Band-aid on; I want milk; I want some more toys; I want another story OK*; and here are some examples of the referential use: *I want the next page* (the next page, of course, having a definite reference or denotation); *I want this* (with *this* having reference to a particular object in the environment); *I want her to wear the blue dress* (where the phrase *her to wear the blue dress* refers to a definite concrete act).

In the examples I have cited there seems to be little ambiguity between attributive and referential use of the noun phrases in object position. In the philosophical literature on these matters there has been considerable discussion of the kinds of examples that do give rise to ambiguity. A typical instance would be: John wants to marry a French girl. Given only this sentence, it is ambiguous whether the reference is to some one particular girl or whether John is looking for a wife, does not have a definite person in mind, but wants her to be a woman who is French. Such examples can also occur with the use of the definite article as well as the indefinite article. For example, Hintikka (1973) cited "John believes that the richest man in town is a Republican." It is ambiguous whether John has in mind some particular individual or simply believes it true that whoever is

the richest man in town, he will turn out to be a Republican.

I have examined Nina's use of *want* for the same kind of ambiguity. It exists with the indefinite article, but so far as I can see not with the definite article. Here are several examples with the indefinite article: *Do you want a pink balloon?*; *her don't want a cup*; *her want a blanket OK*; *I don't want a jersey on*; *I want a toy*. In all these cases, as Hintikka rightly remarked in his own analysis of a different range of examples, additional factual information, in our case the kind of information available in the corpus from preceding sentences or comments on the situation, makes clear whether the usage is attributive or referential.

The question of theoretical interest is what uniform account semantically is to be given of these matters. For example, can the kind of model theory characteristic of elementary formal languages, which are normally extensional, be extended to the kind of language expressing propositional attitudes as found in Nina's speech? If I had asked this question 30 years ago, the answer would almost certainly have been pessimistic and rather negative, because the semantics of modal concepts or propositional attitudes had scarcely been developed. Fortunately, an intense concern with these matters within logic proper in the past three decades has created a considerable logical apparatus, and a deep understanding of the semantical problems involved has developed. In saying this I do not mean to suggest that all the conceptual problems are solved or that the application of current theory to children's speech is simple or straightforward. I do mean to suggest that many powerful and subtle methods are available and can be applied.

The most important theoretical point in these developments is that the semantics of sentences expressing propositional attitudes can be given a precise treatment in terms of the concept of a set of possible worlds.

To illustrate the idea of a set of possible worlds, let me first consider some classical modal concepts before turning to Nina's speech. If I say "It is possible that it will rain tomorrow," then the semantics of this statement is that there is a possible world in which it will rain tomorrow. If on the other hand I say "It is necessary that an object that is red is colored," then I mean that in every possible world this state of affairs must hold. On the other hand, if I say "It is contingently true that Bertrand Russell lived to be more than 90

years old," I mean that in some possible worlds this assertion would be true and in others it would be false. When Nina says "I don't want a jersey on," one interpretation of the semantics of this is that there is a possible world in which Nina does not put a jersey on, and it is in this world that she wants to be. (When I say "one world," I mean usually a set of worlds having this characteristic.) In general when Nina says "I want X," the semantics can be given a precise interpretation in terms of her desire for the actual world to be drawn from a certain set of possible worlds, and she is asking for actions that will make this take place.

(A technical remark is in order about these matters. A tradition exists in the logical and philosophical literature that defines a proposition as a function from possible worlds to truth values. This, for example, was the definition preferred by the late Richard Montague. On the basis of this kind of analysis, we would say that Nina's statement of a want or need expresses a proposition that is a function from possible worlds in which the want is satisfied to truth values. For various reasons, I do not like this analysis. For instance, one of the difficulties of Montague's view is that any two logically equivalent sentences express exactly the same proposition. Rather, I prefer that the structural characteristics of a sentence be an integral part of its expression of meaning. The identification of an utterance expressing a want with the function mapping possible worlds into truth values ignores the grammatical structure of the utterance. On the other hand, I emphasize that in the semantic analysis of such utterances expressing wants the simple theory of denotation discussed earlier is not satisfactory, and a more complicated theory building on the theory of possible worlds is required. For example, once we pass from a single fixed world or model to a set of models or worlds, simple adjectives like *red* no longer denote a set, but at the very least a set in each possible world or, put another way, a function that is a mapping from possible worlds into sets of objects in that world, in each case the set of objects being the set of red objects in that world.)

At this point many of you may feel that I have pulled you a long way from psychological questions to philosophical questions that seem to have little relevance to Nina's thoughts, actions, and language. I wish to urge upon you the thesis that this is not at all the case. Psychologists have

mainly ignored the complexities and subtleties of the expression of propositional attitudes by young children even at their earliest stages. There may be a simpler way of giving a full-scale analysis of these matters, but if there is, it is not known to me, and it is certainly not widely available in the current relevant literature on these matters. What I have hoped to convince you of, and I think in the limited space available I have not been able to do the job adequately, is that already a host of methods and subtle distinctions are available, which we may effectively use for a better understanding of the explicit semantics of children's speech. What I have tried to make evident in my discussion of propositional attitudes is this: Even from the very beginning of a child's speech, in the age from two to three years, the whole battery of semantical problems associated with propositional attitudes, a set of problems among the most subtle in current semantical theory, arise in providing a detailed and accurate theory of children's speech.

Consequence and Paraphrase

In my introductory remarks I mentioned the desirability of changing the classical logical notion of consequence, and I now turn to this topic. In order to give the discussion a focus, I shall relate my remarks about logical consequence and a wider concept of consequence to psycholinguistic discussions of paraphrase and how problems of paraphrase arise in the analysis of the semantics of children's speech.

Frege's definition of paraphrase is that two sentences are paraphrases of each other just when they have the same logical consequences. If we use the characterization of propositions stated above, that is, a proposition is a function from possible worlds to truth values, then we may also characterize in equivalent fashion two sentences as being paraphrases of each other just when they express the same proposition. It is surprising to find this semantical characterization of paraphrase essentially unmentioned in the psycholinguistics studies on the paraphrasing ability of children or adults.

For example, in the careful and extensive study of Gleitman and Gleitman (1970), *paraphrase* is characterized as a notion that is properly thought of as a part of generative grammars, but this seems to me a clear error. Gleitman and Gleitman emphasized that transformations of a sentence can express paraphrases, but in the standard semantical Fregean sense, two sentences that have totally un-

related derivational histories can be logical paraphrases of each other. In practice, moreover, what is used in experimental tests of paraphrasing ability is really a semantic and not a syntactic criterion. The explicit use of model-theoretic semantics would put the experimental studies in this area on a sounder conceptual basis.

Nevertheless, I think there is adequate ground for changing the Fregean definition, which is too stringent. When Nina says things that are ungrammatical to our adult ears, it is usually easy for us to paraphrase what she has said, even without knowledge of the context. Consider the following: *No, I wanna go to what that thing and see if I'm tall; no more presents he doesn't give me; now let me try other Rachel's sunsuit, mommy; I feel better my diaper rash.* On the other hand, the following sentence of Nina's might present some difficulty even within context: *I want to save this on with the same time.*

In paraphrasing Nina's speech or someone else's, we almost always assume without question certain background information and knowledge that is not included in Frege's strict definition of paraphrase in terms of logical consequence. As I mentioned earlier, within model-theoretic semantics it is easy to give a characterization of logical consequence; namely, one sentence is a logical consequence of another if the first sentence is satisfied in any model in which the second is satisfied. In other words, we consider all possible models. But, we can get a less strict notion of consequence by reducing the set of possible models to some smaller set in which basic intuitive knowledge is held rigid across all the models in the set. Two sentences can then be said to be paraphrases relative to this reduced set of models if they both are satisfied in exactly the same models of the reduced subset.

This reduced notion of consequence, which I shall call R-consequence, has other uses than in the treatment of paraphrase. It is also the appropriate concept, in my judgment, for the analysis of questions and answers in children's speech. In the age range I have been mainly discussing, children primarily answer questions by adults, and it is only a year or so later that the tables are turned and they begin asking the questions and expecting answers. For this early stage of answers or the later stage of questions, the concept of R-consequence provides the proper concept for characterizing semantically correct answers to a question. (Notice that I do not say *the* semantically correct

answer, because in general any one of an indefinite number of paraphrases will be accepted as correct.) I return to the importance of questions and answers in children's speech when I discuss problems of verification.

I conclude this article with a discussion of three types of problems: problems of context, problems of process, and problems of verification.

Problems of Context

When Nina says "I need some more" or "I want some too," it is clear that a full semantical account of these utterances is dependent on the context of utterance. This dependence on context is characteristic not only of children's speech, but of much casual adult talk as well. It stands in sharp contrast to sentence tokens of a formal language that are self-contained and timeless in character, or even to mathematical statements or other scientific statements in ordinary language in formal textbook or treatise mode. The way in which the kind of model-theoretic semantics I am advocating can be extended to cover such matters of context has already been indicated in the treatment described for definite articles. I see nothing standing in the way of similar extensions to other problems of interpretation, as in the case of the two examples just cited.

On the other hand, elaboration of the context to give an adequate account of what Nina was perceiving or remembering at the time she was speaking is to extend in quite substantial ways the framework of classical semantics to include concepts and requirements that have been investigated in all their complexity for many years by psychologists. Putting together what we know about remembering and perceiving with the kind of semantic structure for language I have outlined is a formidable theoretical task that has yet hardly begun. It seems to me, however, that this is the direction in which we should try to take account of context and, in the doing, build a much richer psychological model of Nina's and other children's language behavior.

Problems of Process

Building such a model of remembering and perceiving takes us at once to the consideration of process. A proper criticism of the semantic theory I have outlined is that there are no serious considerations of processing. There is no temporal

analysis of the machinery children or adults use for semantic processing of sentences they speak or hear.

This absence of an explicit analysis of process has been brought home to me in a salient way in some of our own research at Stanford University in the past year or so. In attempting to understand these problems of process and how model-theoretic semantics can be applied to the actual production of speech, we have turned to the problem of implementing an ongoing question-answering system for our computer system. We have chosen a domain that has no requirements of context, namely, elementary mathematical language—with an emphasis on the natural language and not on the elementary mathematics. But even here we have found that substantial theoretical extensions have had to be made to the model-theoretic semantics as described here or as found in the standard logical literature in order to have a workable computer program for actual question answering. My younger colleagues, Robert L. Smith and Freeman Rawson, have now advanced this analysis of process a fair distance (see Rawson, 1973). Space does not permit me to compare this work with earlier work by William Wood, Terence Winograd, or other computer scientists concerned with creating computer programs of a similar sort.

One way of describing the situation is similar to what I said about the problem of context. It is not that model-theoretical semantics as such is wrong, but rather that it has to be extended in order to obtain a working model. Just as a theory of remembering and perceiving must be built into an adequate model of a child in order to give a full account of his speaking and listening, so the model-theoretic semantics of even so definite a subject as elementary mathematics must be extended to fixed and definite dynamic ideas about the order in which functions are called, the precedent procedure for processing of given functions, and in general, the many kinds of considerations that enter into the construction of a compiler or interpreter for a computer language.

Problems of Verification

As in psychological theorizing and experimentation in all areas, it is seldom the case that we can construct a theory that is adequate to account for all aspects of the psychological process under investigation. This widespread fact of theoretical incompleteness doubly holds for phenomena as

complex as those of language. Without providing a full theory of remembering, perceiving, or internal processing we can still ask for empirical tests or verification of theoretical concepts such as those of model-theoretic semantics that I have been discussing.

What must be faced is that the verification of a semantic theory is more difficult and less direct than the verification of grammatical theory. For instance, if one writes a grammar for the corpus of a child's speech, it is possible in a direct way to say what percentage of the utterances in the corpus the grammar parses, and if probabilistic criteria are imposed additionally how well it generates utterances with approximately the same frequency as the frequencies observed in the corpus. Verification that the denotations assigned to terminal words or the semantic functions assigned to production rules of the grammar are correct is not amenable to such straightforward and direct attack. It is of course the case that in testing any theory there are areas of intuitive judgment that cannot be reduced to a formal algorithm of verification, and in many cases the semantic analysis given of the utterances of young children by the kind of apparatus I have described can receive widespread intuitive agreement as to the correctness of the analysis. All the same, the central problem of verification is a subtle one and is not easily handled. For example, in his dissertation, Robert L. Smith (1972) gave an extensive semantic analysis of the corpus of Erica. The Erica corpus consists of 27,922 words. Erica was about 32 months old at the time the corpus was collected and thus fits within the range of the corpora of Nina, Philippe, and Lingling. Smith has written a completely systematic model-theoretic semantics for Erica, assigning a semantic function to each production rule of the generative grammar he also wrote for the corpus. The total system is complex and difficult to comprehend in any simple way. The problem arises of how to test in a systematic way that his semantical analysis is correct. Intuition can be tested on each rule, but it is a strain on the viability of intuition when the number of rules is large and some of them are complex. So far as I can see, we have at the present time no direct way to test the correctness of such a systematic semantics. It is a genuine theoretical construction, and we must use classical methods of indirect analysis to test its validity. The difficulty of providing such a direct test is one of the reasons we have been involved in writing a question-

answering computer program for elementary mathematical questions and commands, because the intuitive agreement and understanding of such questions and commands is absolutely sharp and objective in character, and so the correctness of the underlying semantics is subject to a universally agreed upon test. To some extent, this same approach can be extended to the corpus of speech of a young child when the adult speech is recorded as well, for the question-answering pairs can be analyzed in similar fashion, and in many cases a highly objective criterion is possible for evaluating the semantic analysis of the question-answer pairs. All the same, a fair portion of the question-answering between adult and child is not subject to the same sharp test that obtains for elementary mathematical questions.

The other route is to carry only so far the analysis of spontaneous speech and to turn to experimentation for the detailed verification of semantical concepts and theories. It is my present view that this step is essential, and we shall not be able to collect the evidence to persuade the skeptic until comprehensive experiments that adequately test the kind of semantical ideas I have discussed today are performed. Such experimentation is not hopelessly complex and does seem feasible. There is already a useful tradition of experimentation with three- and four-year-old children, especially in the form of the creation of toy or puppet characters that talk and perform simple actions, and it seems possible to build reasonably sharp tests of comprehension into such situations. On the other hand, designing adequately structured experiments that elicit speech from two-year-olds to provide a

clear test of their underlying understanding of what they are saying is not a simple matter. It is an area of methodology that badly needs development, and I call on those of you who are interested for support and help.

In Retrospect

Forty-Six Years

CARL R. ROGERS *Center for Studies of the Person
La Jolla, California¹*

From 1927 to the present time I have been a practicing psychologist. I have made diagnostic studies of children and have developed recommendations for treatment of their problems; in 1928 I developed an inventory of the inner world of childhood which—may Heaven forgive me—is still being sold by the thousands. I have counseled with parents, students, and other adults; I have carried on intensive psychotherapy with troubled individuals—normal, neurotic, and psychotic; I have engaged in and sponsored research in psychotherapy and personality change; I have formulated a rigorous theory of therapy. I have had 40 years of “teaching experience,” fostering learning through both cognitive and experiential channels. I have engaged in facilitating personal development through the intensive group experience; I have tried to make clear the processes of both individual therapy and the group experience through recordings, demonstrations, and films; I have tried to communicate my experience through what now seem to me to be “countless” writings, tapes, and cassettes. I have played my part as a worker in professional associations of psychologists; I have had a continuous, varied, controversial, and richly rewarding professional life.

So it has occurred to me that there might be some interest in the question, What does such a psychologist think about as he looks back on close to a half century of study and work? It is to that question that I will address my remarks. What is my own current perspective on these years, thinking both about my professional life and its various periods of development and change?

¹ This article was the Distinguished Professional Contribution Award address presented at the annual meeting of the American Psychological Association, Montreal, Canada, August 1973.

Requests for reprints should be sent to Carl R. Rogers, Center for Studies of the Person, 1125 Torrey Pines Road, La Jolla, California 92037.

An Astonishing Impact

I believe the major element of my reaction as I look back on my work and its reception is *surprise*. Had I been told, 35 or 40 years ago, of the impact it would have, I would have been absolutely unbelieving. The work that I and my colleagues have done has altered or made a difference in widely different enterprises, of which I will mention several. It turned the field of counseling upside down. It opened psychotherapy to public scrutiny and research investigation. It has made possible the empirical study of highly subjective phenomena. It has helped to bring some change in the methods of education at every level. It has been one of the factors bringing change in concepts of industrial (and even military) leadership, of social work practice, of nursing practice, and of religious work. It has been responsible for one of the major trends in the encounter group movement. It has, in small ways at least, affected the philosophy of science. It is beginning to have some influence in interracial and intercultural relationships. It has even influenced students of theology and of philosophy.

My work has, to my knowledge, changed the life directions and purposes of individuals in France, Belgium, Holland, Norway, Japan, Australia, New Zealand, and South Africa; in 12 foreign countries readers can find some of my work in their own language; if someone wishes to read a complete collection of everything I have written, he will find it—in Japanese. I look with utter astonishment at this long list of statements.

A TENTATIVE EXPLANATION

Why has my work had such a pervasive impact? I certainly do not attribute it to any special genius of my own, and most assuredly not to any farsighted vision on my part. I give full credit to my younger colleagues throughout the years for their

expansion and deepening of my thought and work, but even their efforts do not account for this far-reaching influence. In a number of the fields I have mentioned, neither I nor my colleagues have ever worked, or been involved in any way, except through our writings.

To me, as I try to understand the phenomenon, it seems that without knowing it I had expressed an idea whose time had come. It is as though a pond had become utterly still, so that a pebble dropped into it sent ripples out farther and farther and farther, having an influence that could not be understood by looking at the pebble. Or, to use a chemical analogy, as though a liquid solution had become supersaturated, so that the addition of one tiny crystal initiated the formation of crystals throughout the whole mass.

What was that idea, that pebble, that crystal? It was the gradually formed and tested hypothesis that the individual has within himself vast resources for self-understanding, for altering his self-concept, his attitudes, and his self-directed behavior—and that these resources can be tapped if only a definable climate of facilitative psychological attitudes can be provided.

This hypothesis, so new and yet in a way so old, was not an armchair theory. It had grown out of a number of very down-to-earth steps.

First, I had learned through hard and frustrating experiences that simply to listen understandingly to a client and to attempt to convey that understanding were potent forces for individual therapeutic change.

Second, I and my colleagues realized that this empathic listening provided one of the least clouded windows into the workings of the human psyche, in all its complex mystery.

Third, from our observations we made only low-level inferences and formulated testable hypotheses. We might have chosen to draw high-level inferences and to have developed abstract, untestable, high-level theory, but I think my own earthly agricultural background deterred me from that. (Freudian thinkers chose this second course, and this marks, in my estimation, one of the most fundamental differences between their approach and the client-centered approach.)

Fourth, in testing our hypotheses, we uncovered findings regarding persons and relationships between persons. These findings and the theory that embraced them were continually changing as new discoveries emerged, and this process continues to the present day.

Fifth, because our findings have to do with basic aspects of the way in which the person's own capacities for change can be released and with the way in which relationships can foster or defeat such self-directed change, it was discovered that they had wide applicability.

Sixth, situations involving persons, change in the behavior of persons, and the effects of different qualities of interpersonal relationships exist in almost every human undertaking. Hence, others began realizing that perhaps the testable hypotheses of this approach might have almost universal application, or might be retested or reformulated for use in an almost infinite variety of human situations.

Such is my attempt to explain an awesome and otherwise incomprehensible spread of ideas which began with a very simple question, Can I, by carefully observing and evaluating my experience with my clients, learn to be more effective in helping them to resolve their problems of personal distress, self-defeating behavior, and destructive interpersonal relationships? Who could have guessed that the groping and tentative answers would spread so far?

PSYCHOLOGY'S AMBIVALENCE

You may have noticed an omission in the listing of the areas of impact of my work. I did not say that I and my colleagues have affected academic, or so-called "scientific," psychology. This was not an oversight. I believe an accurate statement would be that we have had very little influence on academic psychology, in the lecture hall, the textbook, or the laboratory. There is some passing mention of my thinking, my theories, or my approach to therapy, but, by and large, I think I have been a painfully embarrassing phenomenon to the academic psychologist. *I do not fit.* Increasingly I have come to agree with that assessment. Let me amplify.

The science and profession of psychology have, I believe, profoundly ambivalent feelings about me and my work. I am seen—and here I must rely mostly on hearsay—as softheaded, unscientific, cultish, too easy on students, full of strange and upsetting enthusiasms about ephemeral things like the self, therapist attitudes, and encounter groups. I have defamed the most holy mysteries of the academic—the professorial lecture and the whole evaluation system—from the ABCs of course grades to the coveted hood of the doctor's degree. I can best be handled by most writers on psychology in

one paragraph as the developer of a technique—the “nondirective technique.” I am definitely not one of the ingroup of psychological acedemia.

The other side of the ambivalence is, however, even more striking. Psychology as a whole, science and profession together, has showered me with honors—many more, I believe, than I deserve. To my amazement I was awarded one of the first three awards for scientific contribution, and this was back in 1956 when I was much more controversial than I am at present. I had been chosen president of the American Association for Applied Psychology. I had been elected president of the American Psychological Association. I had been appointed or elected chairman of important committees and divisions, and these honors often touched me. Yet, never have I been so emotionally affected as I was by the scientific contribution award and its accompanying citation. When I was elected to an office it could have been partly due to my ambition, for I was ambitious to get ahead in my profession. But this award was to me, in some sense, the “purest” recognition I had ever received. For years I had been struggling to objectify knowledge in a potential field of science that no one else seemed to be concerned about. It was not ambition or hope of any reward that pushed me on. In the empirical research itself there was more than a little desire to prove something to others—clearly not a scientific goal. But in the basic phases of the work—the careful observation, the recorded interviews, the hunches as to hypotheses, the development of crude theories—I was as close to being a true scientist as I ever hope to be. But it was clear, I thought, that my colleagues and I were just about the only ones who knew or cared. So my voice choked and the tears flowed when I was called forth, at the 1956 APA Convention, to receive, with Wolfgang Köhler and Kenneth Spence, the first of the awards for a *scientific* contribution to psychology. It was a vivid proof that psychologists were not only embarrassed by me, but were to some extent proud of me. It had a greater personal meaning than all the honors which have followed, including the first award for professional contribution, given last year.

I did enjoy last year's citation, especially the honesty of the statement that I was a “gadfly” to the profession—only now that statement promotes me to the status of “respected gadfly.” I liked that expression of the ambivalence.

Two Struggles

As I look back over the years, I realize I have engaged in two struggles which have professional significance.

STRUGGLE WITH PSYCHIATRY

The first struggle has to do with the determination of many members of the psychiatric profession that psychologists should not be allowed to practice psychotherapy, nor to have administrative responsibility over “mental health” work, especially if this involved psychiatrists. I first met this opposition in Rochester, New York, when our highly successful Child Study Department, a branch of a social agency, was being reorganized in 1939 into a new and independent Rochester Guidance Center. A vigorous campaign, partly aboveboard and partly behind the scenes, was made to discontinue my services as director and to substitute a psychiatrist. There seemed to be no question about the quality of my work. The argument was simply based on the view that a psychologist could not head up a mental health operation—it was simply “not done.” Although we had employed psychiatrists on a part-time basis for years, that suddenly became something that was out of the question. I could not point to any important precedent, nor could I claim the support of any professional group. It was a lonely battle. I am very grateful to the board of directors, who were almost all laymen, for eventually deciding the dispute in my favor. It had been a life-and-death struggle for me because it was the thing I was doing well and the work I very much wanted to continue.

After an interim lull at Ohio State University, the struggle was renewed with even more vigor at the University of Chicago. Not one of the rapid succession of chairmen of the Department of Psychiatry was willing to cooperate with the unorthodox fledgling Counseling Center. Finally, one of these men demanded of the University administration that the Counseling Center be closed, since its members were practicing medicine (namely, psychotherapy) without a license. There was still no professional support for our activities from the APA or any other psychological organization. I mounted a blistering counterattack, with all the evidence I could muster. Again I am grateful, this

time to the chancellor of the University, for his (to me) fair-minded consideration and his suggestion to psychiatry that they drop their demand, which they did. These are the only two times I engaged in open combat with psychiatry. For the most part, my strategy has been twofold. I have endeavored to reconcile the two professions in their pursuit of a common goal. I have also tried to move ahead so rapidly and so far that the right of psychologists to practice in a field in which they were preeminent in research, and fully equal in practice and in theory building, could not be challenged.

But when pushed into a corner, as on these two occasions, I can fight with all the effectiveness that one develops in a family of six children. People who know only my thoughtful or gentle side are astonished at my attitude and behavior in a situation of all-out war. I should, in warning, have raised the banner of the early colonies, on which was emblazoned a rattlesnake and the motto "Don't tread on me!"

I am happy to say that at the University of Wisconsin my joint appointment in psychology and psychiatry was a pleasant resolution of these struggles. Indeed, I initiated the formation of a group of psychologists and psychiatrists who gradually defused an incipient legal and legislative battle which was splitting the two professions in that state.

STRUGGLE WITH BEHAVIORISTIC PSYCHOLOGY

The other struggle of my professional life has been on the side of a humanistic approach to the study of human beings. The Rogers-Skinner debate of 1956 is one of the most reprinted writings in the psychological world. It would be absurd of me to try to review that continuing difference in any depth. I will simply make a few brief statements as I look back over these years.

To avoid misunderstanding, let me say immediately that I concur with the idea that the theory of operant conditioning, its development and its implementation, has been a creative achievement. It is a valuable tool in the promotion of certain types of learning. I do not denigrate the contribution it has made. But this is not the basis of divergence.

Let me also say that I have a great personal respect for Fred Skinner. He is an honest man, willing to carry his thinking through to its logical conclusions. Hence, we can differ sharply, without damaging my respect for him. I was invited by several periodicals to respond to *Beyond Freedom*

and *Dignity* (Skinner, 1971) and declined primarily because I felt he had a right to his views. My one disappointment in regard to Skinner is his refusal to permit the nine-hour confrontation we held at the University of Minnesota in Duluth to be released. It was all taped and is the deepest exploration in existence of the issues between us. All of the other parties to the meeting had understood that it was agreed that the tapes, or transcripts of them, or both, would be released. After the meeting, Skinner refused his permission. I feel the profession was cheated.

I have come to realize that the basic difference between a behavioristic and a humanistic approach to human beings is a *philosophical* choice. This certainly can be discussed, but cannot possibly be settled by evidence. If one takes Skinner as of some years ago—and I believe this is his view today—then the environment, which is part of a causal sequence, is the sole determiner of the individual's behavior, which is thus again an unbreakable chain of cause and effect. All the things that I do, or that Skinner does, are simply inevitable results of our conditioning. As he has pointed out, man acts as he is forced to act, but as if he were not forced. Carried to its logical conclusion, this means, as John Calvin concluded earlier, that the universe was at some point wound up like a great clock and has been ticking off its inexorable way ever since. Thus, what we think are our decisions, choices, and values are all illusions. Skinner did not write his books because he had chosen to present his views, or to point to the kind of society he values, but simply because he was conditioned to make certain marks on paper. Amazingly to me, he admitted as much in one session in which we both participated.

My experience in therapy and in groups makes it impossible for me to deny the reality and significance of human choice. To me it is not an illusion that man is to some degree the architect of himself. I have presented evidence that the degree of self-understanding is perhaps the most important factor in predicting the individual's behavior. So for me the humanistic approach is the only possible one. It is for each person, however, to follow the pathway—behavioristic or humanistic—that he finds most congenial.

Saying that it is for the individual to decide is not synonymous with saying that it makes no difference. Choosing the humanistic philosophy, for example, means that very different topics are chosen for research and different methods for vali-

dating discoveries. It means an approach to social change based on the human desire and potentiality for change, not on conditioning. It leads to a deeply democratic political philosophy rather than management by an elite. So the choice does have consequences.

To me it is entirely logical that a technologically oriented society, with its steady emphasis on a greater control of human behavior, should be enamored of a behavioristic approach. Likewise, academic psychology, with its unwavering insistence that "the intellect is all," has greatly preferred it over the humanistic approach. If the university psychologist accepted the latter view, he would have to admit that he is involved, as a subjective person, in his choice of research topics, in his evaluation of data, in his relationship to students, in his professional work. The comfortable cloak of "objectivity" would necessarily be dropped, exposing him as a vulnerable, imperfect, subjective being, thoroughly engaged, intellectually *and* emotionally, objectively *and* subjectively, in all his activities. This is understandably too threatening.

Let me simply add that what is really at issue is the confrontation of two paradoxes. If the extreme behaviorist position is true, then everything an individual does is essentially meaningless, since he is but an atom caught in a seamless chain of cause and effect. On the other hand, if the thoroughgoing humanistic position is true, then choice enters in, and this individual subjective choice has some influence on the cause-and-effect chain. Then, scientific research, which is based on a complete confidence in an unbroken chain of cause and effect, must be fundamentally modified. I, as well as others, have attempted partially to explain away this dilemma—my own attempt was in a paper entitled "Freedom and Commitment" (Rogers, 1964)—but I believe we must wait for the future to bring about the full reconciliation of these paradoxes.

In all candor I must say that I believe that the humanistic view will, in the long run, take precedence. I believe that we are, as a people, beginning to refuse to allow technology to dominate our lives. Our culture, increasingly based on the conquest of nature and the control of man, is in decline. Emerging through the ruins is the new person, highly aware, self-directing, an explorer of inner, perhaps more than outer, space, scornful of the conformity of institutions and the dogma of authority. He does not believe in being behaviorally shaped, or in shaping the behavior of others. He

is most assuredly humanistic rather than technological. In my judgment he has a high probability of survival.

Yet, this belief of mine is open to one exception. If we permit one-man control, or a military take-over of our government—and it is obvious we have been (and are) perilously close to that—then another "scenario" would take place. A governmental-military-police-industrial complex would be more than happy to use scientific technology for military and industrial conquest and psychological technology for the control of human behavior. I am not being dramatic when I say that humanistic psychologists, emphasizing the essential freedom and dignity of the unique human person, and his capacity for self-determination, would be among the first to be incarcerated by such a government.

But enough of this issue. I have strayed into the future. Let me return to my retrospective look and to some less serious reflections.

Two Puzzlements

There are two very different issues which have puzzled me; one of the minor, the other of deeper concern.

REGARDING THEORY

By 1950, I wondered increasingly if my thinking could be put into a coherent theoretical form. At about this time came a request from Sigmund Koch (1959-1963) to contribute to his monumental series of volumes, *Psychology: A Study of a Science*. This was just the slight nudge I needed, and for the next three or four years I worked harder on this theoretical formulation than on anything I have written before or since. It is, in my estimation, the most rigorously stated theory of the process of *change* in personality and behavior which has yet been produced. As one young psychologist with a background in mathematics said to me recently, "It is so precise! I could restate it in mathematical terms." I must confess this is close to my opinion.

I was very pleased that it would be in Koch's series, because I felt sure that these volumes would be studied by graduate students and psychologists for years to come. I do not have exact data, but I suspect these volumes are in fact very little used. Certainly my chapter "A Theory of Therapy, Personality, and Interpersonal Relationships as De-

veloped in the Client-Centered Framework" is the most thoroughly ignored of anything I have written (Rogers, 1959). This does not particularly distress me, because I believe theories too often become dogma, but it has, over the years, perplexed me.

REGARDING CREATIVE LEADERSHIP

The second puzzlement is of a different order. In my younger years, while I was not a hero-worshiper, I definitely looked up to a number of men whom I felt were "real psychologists," whereas I existed on a poorly accepted fringe. I remember the community and professional furor when Leonard Carmichael was brought to the University of Rochester in 1936 as chairman of psychology: a special laboratory equipped to his specifications, a cluster of fellowships provided for his students, every acknowledgment paid to his brilliance and leadership. There was probably some envy in my attitude, as I labored away in a ramshackle frame building set aside for the Child Study Department of the Society for the Prevention of Cruelty to Children, but my feeling was mostly one of admiration and expectancy. I felt the same way toward perhaps a half-dozen others—better trained in psychology than I, in my judgment more brilliant, with books and research studies already to their credit. Here were the men who would produce the great ideas in psychology, who would exert the same kind of intellectual and world leadership as that of outstanding chemists, physicists, and astronomers. I had no doubt at all that I had picked those who, a generation later, would be the preeminently creative and productive leaders of our science.

In every case I have been mistaken. Carmichael, since I have mentioned his name, has gone on to become a revered administrator, operating in the highest levels of the establishment. The others I selected have also had perfectly reputable careers, some outside of and some in psychology. But the dazzling promise of their younger years has not been fulfilled. For some reason this has puzzled me very deeply, because they have one attribute in common. They have lost any truly vital *creative* interest in psychology. Why? Were their interests too narrow and unsatisfying as they grew older? Did they lack any basic conviction or philosophy which might have guided their work? Did their efforts come to seem to them irrelevant to the larger social scene, their contributions too pic-

ayune? Was their initial work done primarily to impress their fellow psychologists, a motive which declines in importance with age? Did they endeavor to stand on and defend their early work, thus inhibiting themselves from reaching out into the creative unknown? I do not know. It has thoroughly perplexed me and made me very wary indeed of trying to pick prospective leaders of creative thought.

The Sources of My Learnings

As I try to review all of the rich streams of thought and experience which have fed and are feeding my professional life, I can discriminate several of the most important sources.

CLIENTS AND PARTICIPANTS

First and overwhelmingly foremost are my clients in therapy and the persons with whom I have worked in groups. The gold mine of data that resides in interviews or group sessions staggers me. There is, first of all, the gut-level experience, which absorbs the statements, the feelings, and the gestures, providing its own complex type of learning, difficult to put into words. Then there is the listening to the interchanges in the tape recording. Here are the orderly sequences that were missed in the flow of the experience. Here, too, are the nuances of inflection, the half-formed sentences, the pauses, and the sighs, which were also partially missed. Then, if a transcript is laboriously produced, I have a microscope in which I can see, as I termed them in one paper, "the molecules of personality change." I know of no way of so combining the deepest experiential learning with the most highly abstract cognitive and theoretical learnings as the three steps I have mentioned: living the experience on a total basis, rehearsing it on an experiential-cognitive basis, and studying it once more for every intellectual clue. As I said earlier, it is perhaps the most valuable and transparent window into the strange inner world of persons and relationships. I feel that if I subtracted from my work the learnings I have gained from deep relationships with clients and group participants, I would be nothing.

YOUNGER COLLEAGUES

The second most important source of stimulation for me is my symbiotic relationship with younger

people. I do not understand this mutual attraction. I just feed upon it. In my youth I surely learned many things from my elders, and at times I have even learned from colleagues in my own age bracket, but certainly for the last 35 years any real learnings from professional sources have come from those who were younger. I feel a deep gratitude to all the graduate students, younger staff members, and inquiring youthful audiences who have educated and continue to educate me. I know that for many years, given the chance to associate with professional colleagues of my age, or with a younger group, I inevitably drift to the latter. They seem less stuffy, less defensive, more open in their criticism, more creative in suggestion. I owe them so much. I started to write down examples, but to give a few would be unfair to the hundreds who have so freely contributed their ideas and their feelings in a relationship which has also lighted sparks of creative thinking in me. They have excited me, and I have excited them. It has, I hope, been a fair exchange, though I often feel I have gained more than I have given. I feel a great pity for those persons I know who are growing into old age without the continuing stimulation of younger minds and younger lifestyles.

SCHOLARLY READING

Then much farther down the scale I would put what is often regarded as a major source of learning, the printed page. Reading, I fear, has most of its value for me in buttressing my views. I realize I am not a scholar, gaining my ideas from the writings of others. Occasionally, however, a book not only confirms me in what I am tentatively thinking, but lures me considerably further. Kierkegaard, Buber, and Polanyi, for example, would fall in that category. But I must confess that when I wish to be scholarly, serendipity plays a very important part. Serendipity, in case you have forgotten, is "the faculty of making fortunate and unexpected discoveries by accident." I have an eerie feeling that I have that faculty. Let me give you the latest examples. In preparing a current paper, "The Emerging Person: A New Revolution," I was aware of a few of the writers who were presenting similar views. But then Fred and Anne Richards (1973) sent me a copy of their book *Homonovus*, just off the press. It was most timely. John D. Rockefeller III (1973) (I have had two contacts with him) likewise sent me a

copy of his book *The Second American Revolution*, which was also highly pertinent. Then I was talking with a friend from northern California about my fantasies for my APA paper and he said, "Did you read the article by Joyce Carol Oates in the *Saturday Review*?" I had to confess complete ignorance not only of the article but of the author. His Xerox copy of the essay not only gave support to my view, but opened my eyes to a whole new facet of modern fiction. So, while one section of that paper may make it appear that I spent days or weeks researching in the library, at least half of that impression is due to serendipity. It has been a very frequent aid in my life.

My Concern with Communication

Still peering back—through my neck is getting stiff from that posture—I can see what is perhaps one overriding theme in my professional life. It is my caring about communication. From my very earliest years it has, for some reason, been a passionate concern of mine. I have been pained when I have seen others communicating past one another. I have wanted to communicate myself so that I could not be misunderstood. I have wanted to understand, as profoundly as possible, the communication of the other, be he a client or friend or family member. I have wanted to *be* understood. I have tried to facilitate clarity of communication between individuals of the most diverse points of view. I have worked for better communication between groups whose perceptions and experiences are poles apart: strangers, members of different cultures, representatives of different strata of society. To give adequate examples would compass the length of my career. I will cite only one. The filmed experience of a group involved in the drug scene included straight individuals, such as a narcotics agent, and "stoned" individuals, including a convicted drug pusher. There were blacks and whites, the young and middle-aged, ghetto products and members of the middle class. The group process by which communication and closeness became a living part of this diverse group is an experience I shall never forget. It is unfortunate that the film's title, *Because That's My Way*, chosen for us, catches so little of the vivid interchange which occurred (Station WQED, 1971).

This obsession with communication has had its own unexpected rewards. I held a half-hour interview with a young woman named Gloria (some of

you may have seen the film) and a deeply communicative contact was established. To my complete surprise, she has kept in occasional touch with me for eight years, primarily in appreciation for the closeness we achieved. With Randy, the convicted drug pusher in the drug film, I was in constant correspondence for more than a year. Mr. Vac, one of my clients in our complex research on psychotherapy with schizophrenics, tracked me down after eight years with a "Hi, Doc," to let me know that he was still doing well and had never returned to the state hospital, even for a day. I think such rewards are savored more as the years go by.

In Sum

So I can sum up my informal look at my professional past by saying:

I am amazed at the impact of our work;

I have a dim comprehension that the time was ripening for it;

I look with amusement and affection at the ambivalence I have created in psychology;

I see with satisfaction the war with psychiatry concluding;

I am pleased to have played a part in the continuing drama of the behavioristic versus the humanistic philosophy;

I am puzzled and humbled by the disregard of what I see as my theoretical rigor;

I am perplexed by the later careers of some of the truly shining lights I have seen;

I am especially grateful for the gift of vital learnings from the people whose development and growth I have endeavored to facilitate;

I have confidence in the young, from whom I have continuously learned;

I discern more sharply the theme of my life as having been built around the desire for clarity of communication, with all its ramifying results.

The Now—and the Future

I should stop here, but I cannot. It is always a strain for me to look backward. It is still the present and the future which concern me most. I cannot close without a quick overview of my current interests and activities.

I am no longer actively engaged in individual therapy or empirical research. (I am finding that after one passes 70, there are physical limitations

on what one can do.) I continue to engage in encounter groups when I believe they might have significant social impact. For example, I am involved in a program for the humanizing of medical education. Up to the present, more than 200 high-status medical educators have been involved in intensive group experiences which appear to be more successful in facilitating change than we had dared hope. Perhaps more humanly sensitive physicians will be the result. It certainly represents a new area of possible impact.

I have also helped to sponsor, and have taken some part in, interracial and intercultural groups, believing that better understanding between diverse groups is essential if our planet is to survive. The most difficult group was composed of citizens of Belfast, Northern Ireland. Represented in the group were militant and less militant Catholics, militant and less militant Protestants, and English. The film of that encounter portrays its difficult and partial progress toward better understanding—a first step on a long road. I see it as a small test tube attempt which might be utilized in greater depth and much more widely.

I continue to write. I recognize that while my whole approach to persons and their relationships changes but slowly (and very little in its fundamentals), my interest in its applications has shifted markedly. No longer am I primarily interested in individual therapeutic learning, but in broader and broader social implications. Perhaps the titles of some of my recent papers (completed or in progress) will best give you a glimpse of where I am in my present work. The approximate titles are, "My Philosophy of Interpersonal Relationships and How It Grew"; "Bringing Together the Cognitive and the Affective-Experiential in Education"; "Some New Challenges to Psychology"; "Some Social Issues Which Concern Me"; "The Emerging Person: A New Revolution." As I state these, the question arises in my mind, as it often has in the past, "Am I spreading myself too thin?" Only the judgment of others can answer that question at some future date.

And then I garden. Those mornings when I cannot find time to inspect my flowers, water the young shoots I am propagating, pull a few weeds, spray some destructive insects, and pour just the proper fertilizer on some budding plants, I feel cheated. My garden supplies the same intriguing question I have been trying to meet in all my professional life: What are the effective conditions for growth? But in my garden, though the frustra-

tions are just as immediate, the results, whether success or failure, are more quickly evident. And when, through patient, intelligent, and understanding care I have provided the conditions that result in the production of a rare or glorious bloom, I feel the same kind of satisfaction that I have felt in the facilitation of growth in a person or in a group of persons.

Scientific Awards Announcement

The Committee on Scientific Awards is accepting nominations for its award program. The Committee selects up to three persons as recipients of the Distinguished Scientific Contribution Award who, in its opinion, have made the most distinguished theoretical or empirical contributions to scientific psychology in recent years.

A new award, the Distinguished Contribution for Applications in Psychology, has been authorized by the Board of Directors and will be given for the second time this year. This award will be presented to an individual who, in the Committee's opinion, has engaged in a program of research which is systematic and applied in character.

The awards are subject to the following limitations: (a) members of the Committee, former recipients of the awards, the President and the President-elect of the APA shall be ineligible. (b) The Committee shall seek diversity in selecting recipients, avoiding as far as possible the selection of more than one person representing a specialized topic, a specific material, a given method, or a particular application.

Names and appropriate information which will guide the Committee on Scientific Awards in conducting an intensive career review and evaluation should be forwarded to Office of Scientific Affairs, American Psychological Association, 1200 Seventeenth Street, N.W., Washington, D.C. 20036. *Deadline for nominations is March 1, 1974.*

Salvation and Its Vicissitudes

Clinical Psychology and Political Values

BENJAMIN BEIT-HALLAHMI *University of Michigan Counseling Center*¹

Discussions of values, as opposed to discussions of technology and ethics, are relatively rare among clinical psychologists and constitute only a limited component of graduate training. One major reason for this is that many clinical psychologists consider their technology to be value free. Personally, I find this view rather amusing. I can recall several case conferences when a statement by one participant was reacted to by another with a victorious, critical "But this is a value judgment!" My reaction is, "But I thought everything we were doing here was based on value judgments." This last statement is likely to enhance my reputation as a cynic who has little respect for the sacred cows of the profession and the delicate feelings of his colleagues. It is interesting to note that those who emphasize the role of values in professional work are often labeled "cynics," and those who remind us of glaring inequalities and exploitation are labeled "materialists," while those who deny the importance of values and morality and justify exploitation and inequality are, apparently, idealists and purists. What becomes clear is that, for most psychologists, there is no need to talk about values, because they are taken for granted and are agreed on by a majority of their professional colleagues. There is little need to discuss what we all agree about; discussion is more likely to arise in cases of conflict. What we all take for granted may be ego syntonic, personally and professionally, may be consistent with our self-image, and is probably consistent with our self-interest and the need for survival in this society, but it is exactly what we take for granted that most clearly reflects our biases.

What we normally deal with when we talk about values in psychology are "professional ethics" (American Psychological Association, 1963). Professional ethics, as defined by the majority of psychologists, deal with the rules of our game vis-à-vis society. They reflect both an honest concern with the rights of others and the wish to preserve our professional monopoly and privileged status, but these rules of professional conduct stay within the realm of technical questions and our reputation as good citizens. Professional ethics concentrate on the moral implications of our relationship with the client, but do not deal with the moral implications and the political consequences of this relationship as they extend to other areas of the client's life.

In our actions as clinical psychologists, we express our implicit theories of human nature and human society. Normally we discuss theories of human nature and refrain from talking about our theories of society. It is assumed that we can leave the task of dealing with the nature of society to others, and the decision to do that relegates the political implications of psychology to the professional unconscious, where it is destined to lie repressed unless uncovered through some radical treatment or some severe trauma (cf. Simon, 1970). Analyzing implicit value statements in our professional work will lead us to focus on the political implications of our daily activities. The relationship of professional psychology to the rest of society and especially its political implications are evidently open to several interpretations. One view simply asserts that psychologists always serve those in power, whether they are aware of it or not. Another view regards psychology as a major force working for cultural change or cultural rebellion. We will have to check both views against reality and will find that the truth does *not* lie somewhere in between.

¹ This article is partly based on a paper presented at the Michigan State University Conference on Clinical Psychology, East Lansing, May 1973.

Requests for reprints should be sent to Benjamin Beit-Hallahmi, who is now at the Department of Psychology, University of Haifa, Haifa, Israel.

Szasz's (1961) analysis of the psychiatric profession seems pertinent to what most clinical psychologists do. Psychiatric activity, according to Szasz, is a form of social control. The psychiatric professional activity is a combination of three roles: (a) theoretical scientist—an expert on game-playing behavior; (b) social engineer—one who sorts out players and assigns them to games they can play; and (c) social manipulator—one who influences people to induce them to play, or cease to play, certain games. In the psychiatrist's main role as a social engineer, he sorts people into pigeonholes of "identities" in which they belong, and in his role as a social manipulator, or therapist, he makes sure that they stay there. The extent to which most therapists foster social conformity and social control, rather than self-actualization, is clear in a nationwide survey of therapists by Goldman and Mendelsohn (1969).

Our dilemma is summarized in a quotation from the play *The Cocktail Party*, by T. S. Eliot (1965). Eliot's heroine goes to a psychiatrist and starts her interview with the following statement: "I should really like to think there's something wrong with me—Because, if there isn't, then there's something wrong . . . with the world itself . . . [p. 132]." Our clients, when they come to us, ask the same question: Is there something wrong with them, or is there something wrong with the world around them? And with few exceptions, psychologists tell them that there is something wrong with them and nothing wrong with the world. We usually ignore the possibility of structural social problems, which in turn cause some of the discomfort in our clients. The importance of interpersonal and social conflicts tends to be obscured by our preoccupation with internal conflicts (cf. Hurvitz, 1973; Mills, 1959). As Szasz (1970) suggested, the psychological approach is used to de-ethicize and depoliticize ethical and political issues. By deciding to become "neutral" or "irrelevant" we are taking a significant political stand.

In individual work and in theorizing about groups, we formulate explanations for emotional states, especially those likely to create conflict. We do have ideas about the sources of interpersonal conflict and personal unhappiness. We normally refer to anger and sadness as "hostility" and "depression," and a crucial part of our social role is to explain their sources. We are called on to

explain the sources of oppression and the way it is felt by the individual. The major question is whether the sources of oppression are external or internal. The traditional psychodynamic view saw the disturbed person as oppressed by his symptoms, inhibitions, and other inappropriate behaviors (Hartmann, 1960). This view of oppression as mainly internal is still accepted by most psychologists today. Those who explain their problems and oppression as being caused by external sources are rejected by us as externalizing, defending themselves against the more demanding internal frame of reference.

A major function of psychologists today is to rationalize inequality, or, in more elegant language, to explain the differential allocation of rewards in society. Psychologists are called on to make individual judgments as to who shall be rewarded, and they are also involved in more general explanations as to who shall inherit the earth, and why. The way psychologists rationalize inequality is by telling us that people at the bottom of the social ladder are lower on IQ tests, show less ego strength, have weaker superegos, and are unable to delay gratification. (See Hollingshead & Redlich, 1958; Levy, 1970; Mehlman & Fleming, 1963; Reissman, Cohen, & Pearl, 1964.) If only psychology had been sufficiently developed in the 1840s in the United States, we would have read a psychological analysis of slavery, describing slaves as "unable to delay gratification, low on frustration tolerance, having psychopathic tendencies, scoring lower on intelligence tests, and in general being unmotivated, impulsive, and violent." An interesting conclusion would have been that slavery is a psychological syndrome, transmitted from generation to generation. Support for this conclusion would have come from the observation that children born to slaves tend to become slaves themselves. If the above description seems absurd, one should look at the way psychologists discuss the problem of poverty today; then this absurd pattern will become familiar. (See Billingsley, 1970; Herzog, 1970; Ryan, 1971.) The extent of person blaming as a strategy in psychological research of social problems and the various forms this technique takes are brilliantly described and illustrated by Caplan and Nelson (1973):

The psychological view of human suffering is discovered to be, upon a closer look, a repetition of the old conservative morality: Man is by nature sinful and corruptible; most of an individual's suf-

fering is blamed on himself in a variety of ways. The modern psychological way of doing it is by describing a variety of personality deficiencies: lack of motivation, inability to delay gratification, low frustration tolerance, "psychopathic personality," etc. When we look at psychology as a mechanism of social control, an interesting analogy comes to mind. If we combine the emphasis on individual responsibility, internal causation, and individual solution to problems, it all sounds a little like a call for soul searching and individual salvation, and indeed it may be. The similarity between the functions of religion and psychology was also noted by London (1964), who described the enterprise of psychotherapy as "the salvation of secular man" and psychotherapists as "secular priests." When we look at the content of what both psychology and religion offer the individual, the similarity is rather striking: Both move away from the social and material world, to deal with the invisible world of feelings and fantasies. Both offer salvation at the individual and internal level, not in any social, political, or economic way. Both psychology and religion tell us that the road to happiness is through individual change and not a change in the world around the individual.

IS PSYCHOLOGY A FORCE FOR SOCIAL CHANGE?

Is psychology indeed the opium of the people, as I was implying above? Most psychologists see themselves as part of a movement toward positive social change and will be terribly offended if we suggest to them that they are part of a social control mechanism. Many psychologists have an image of themselves and their profession as counterdependent, rebellious, and critical of society. Many clinical psychologists see themselves as the vanguard of a new humanistic revolution. Recent developments in the technology of psychotherapy and especially new group approaches are hailed as signifying a new age and a "human potential movement." Some of the claims of this movement rest on the assumption that the atmosphere of social groups and organizations can change with the help of proper therapeutic procedures, and the age of Aquarius will dawn upon us as a result of greater individual awareness and liberation.

A popular book detailing "awareness exercises" is appropriately entitled *What to Do Till the Messiah Comes* (Gunther, 1971). The title implies an expectation of a major change in this

world and in this society. But until this eschatological event comes, the reader is offered a series of experiences to tide him over. These are all temporary measures, but that is what we must do while we are waiting for real change. We can change our very private environment, while the Messiah is expected to do the rest. This anecdote raises some serious questions: (a) Can psychology change society in any way? (b) Do we have the potential or power to bring about change? (c) What is the real effect of the things we do "until the Messiah comes"? Is it possible that all these temporary measures may be delaying change?

One of the claims heard most often from psychologists who are involved in changing individuals goes like this: "We help people get their heads together, so that they can change the world around them." As Halleck (1971) suggested, helping people get their heads together often results in the elimination of their desire to change the world. People who are thoroughly pleased with their lives do not make good revolutionaries. Both Halleck (1971) and Halmos (1970) showed how psychological interpretations and emphasis on individual motivation neutralize potentially political energy.

One answer to the question of gap between what psychologists are doing and what they think they are doing has to do with the social origins of people who become clinical psychologists. Marginality is central in the experience of clinical psychologists, both individually and as a group. As a group, psychologists are notoriously deviant. They differ from majority views in both attitudes and life-styles (Roe, 1956). They are openly critical of social norms and social roles. How can we integrate this view of psychologists with their role as social engineers and social controllers?

There is indeed a paradox here, the paradox of those who are marginal and deviant and who are put in a position of being controllers and resocializers. We might say that the minimally deviant psychologists are resocializing the extremely deviant, those who are defined as "mentally disturbed," "mentally ill," or "criminal." Society's way of recruiting social controllers is based on both individual dynamics and societal needs. Often, the social regulator is very close to those he regulates, both in dynamics and origins. We often comment on how policemen are very similar to those they arrest, in both dynamics and social origin. The difference between the cop and the robber is that the cop becomes aware of his impulses early enough

to control them by becoming a controller. Similarly, choosing the career of a social engineer may have something to do with recognizing one's own impulses and defending against them. In terms of individual dynamics, we may speculate that this career choice is related to an incomplete identification with the parents in early childhood. This identification is completed by assuming the parental role in work with deviants and by identifying at the same time with the client, who is rebuilding his own identification. In terms of individual mobility, choosing the career of a psychologist means for most individuals who make this choice moving upward and assimilating into the majority because most clinical psychologists come from socially marginal groups (Henry, Sims, & Spray, 1971).

Recent Developments and Their Implications

Recent developments in professional practice can be looked at from the perspective of their relationship to the traditional view presented above, either as challenges to, or derivatives of, traditional approaches. Most of the changes in practice originate from the internal frustrations and failures of the profession itself and present themselves as innovations in technology. Some of the changes, mainly those that arose in response to external pressures, may involve a different value perspective.

Perhaps the major development over the last 10 years in terms of clinical practice has been the rise (maybe the triumph) of behavior modification. In terms of the values and the political views described so far, behavior modification is paradoxical because it is both the embodiment and the natural consequence of the conservative trend in psychology and the only psychological school that is openly and consciously value laden. We should commend our colleagues who practice behavior modification for their honesty in stating their value preferences. Most of them are quite open about the fact that they work to enforce social norms and prevent deviance. Contrary to other therapists, they are ready to tell us exactly what kinds of changes they want to bring about in their clients, and why. Their starting point is always what is socially desirable and socially acceptable. One of the promoters of behavioral approaches to deviance, J. V. McConnell (1970), suggested the following:

We should try to regulate human conduct by offering rewards for good behavior whenever possible instead of

threatening punishment for breaches of the law. We should reshape our society so that we all would be trained from birth to want to do what society wants us to do [p. 74].

The behavioral approach recognizes the importance of the environment in shaping the individual, but attempts to reshape the individual, rather than the environment, when dealing with human suffering and dissatisfaction. In this respect, behavior modification is in total agreement with most other clinical approaches. Philosophically, behavior modification is the logical result of the "end of ideology" and the "end of values" movement in clinical psychology, the reduction of all moral questions to technical ones. "End of ideology" theories, in both psychology and politics, are promoted by conservative forces. The assumption behind them is that of a broad consensus, which unites most members of society and most members of the profession, so that only "technical" problems remain to be solved (cf. Halmos, 1970). Behavior modification is the logical result of our emphasis on "functioning" and on our "big machine" model of society. We start with the belief that the big machine is all right; we just have to keep it oiled and running. Individuals, who can best be conceptualized as little machines, should adjust to the big machine, and they too should be kept oiled and running. Psychologists help people adjust to the reality of the big machine.

Other changes in practice present more of a challenge to the narrow ecological view of the causation of human suffering because they go beyond the individual and attempt wider system intervention. The newer developments of family therapy and network therapy show that the preoccupation with individual causation can be constructively overcome. These newer approaches also give due recognition to what is going on within the family at present, and not only what was going on within the family 20 and 30 years ago. Dealing with systems may lead psychologists to look at wider and more encompassing ones. It is impossible to ignore the continuity between the family and society as a whole, and so psychologists are already looking at whole communities and may find themselves looking at whole societies.

More serious challenges to the traditional model of the person in psychology come from those who attack the basic definition of deviance. The drive toward politicalization of private problems offers us concrete examples of an alternative way of viewing our clients. The emphasis on what human beings

have in common internally is countered by the new emphasis on what people have in common externally, such as race and sex. We are used to dealing with individual and universal insecurities involved in the process of growing up in human society. The new approaches emphasize the insecurities involved in growing up as a member of a social group. The differences between growing up powerful and growing up powerless, growing up upper class and growing up working class, growing up white and growing up black, all lead to differences in psychological experiences and self-concept.

The experiences of every woman, black, and Chicano are affected by their social positions. Belonging to an oppressed group in these cases is one of the major determinants of individual experience. Politicizing women's problems is significant because women make up the majority of our clients. The feminist viewpoint implies that there are external forces and necessities that shape women's behavior into forms that are then regarded as deviant or pathological. The external social forces are those that determine what appears to be prevalent forms of psychopathology. The hysterical, depressed housewife has some pretty good reasons to be depressed, and identity conflicts in college women are a result of reality pressures. When we look at minority groups, the radical viewpoint emphasizes reality factors in the causation of personal difficulties and underscores the relativity of clinical concepts.

The lessons of "community mental health" and studies in psychiatric "epidemiology" are quite clear. They show that the poor and minority groups are "high-risk" populations in terms of "mental health," which means that members of these groups are more likely to become inmates in mental hospitals and prisons. One of the daring suggestions of the recent Nader's Raiders' report on community mental health was that employment opportunities and better housing could do more for the "mental health" of the poor than could community "mental health" centers. This suggestion was properly ignored by the "mental health" professionals because it obviously indicates defensive externalization.

Many psychologists have become sensitized to the problems of women and are less likely to take a totally individualistic position when looking at the problems of individual women. Many are recognizing more and more the effects of the social situation on members of minority groups and are

willing to examine critically the social consequences of psychological measurements and definitions. We can then generalize and suggest that there are general social conditions affecting most members of this society, not only minority groups. Growing up and living in a society that regards and treats people as commodities affects every individual's self-concept, confidence, and abilities (Marcuse, 1964, 1966). In working with individual clients and in our attempts to generalize from work with individuals, we have to recognize social and political realities. Both the psychologist and the client are subject to enormous social pressures. Clients come to us often when they have to make real-life decisions, and all too often we tend to ignore the impact of political and economic realities to which they respond. What we are all interested in, or, that is, what we say we are interested in, is the maximal actualization of human potential. The question before us is whether such an actualization is possible without a major transformation of society. Most psychologists today are committed to a viewpoint which sees self-actualization as totally dependent on the individual and are totally satisfied with a role definition which demands that we leave society intact, while changing only the individual. Those who are committed to a different choice of values are in the unenviable position of reminding the majority of psychologists of its repressed responsibilities.

Gold Medal Award

The Trustees of the American Psychological Foundation invite members of the American Psychological Association to nominate candidates for the Gold Medal Award. The Award is given to an American psychologist in recognition of a distinguished and long-continued record of scientific and scholarly accomplishments. The Award is limited to psychologists 65 years of age or older and is also limited to those residing in North America. Nominations should be accompanied by a statement highlighting the accomplishments of the nominee. They should be addressed to: Secretary, American Psychological Foundation, 1200 Seventeenth Street, N.W., Washington, D.C. 20036, to be received no later than March 15, 1974. Decisions will be made by the Trustees of the Foundation.

The History of Psychology Revisited

Or, Up with Our Foremothers

MAXINE D. BERNSTEIN *Richmond College, City University of New York*

NANCY FELIPE RUSSO *American University*¹

Test yourself (no peeking):

Q1. Who were the first persons to use the term *projective technique* in print?

Q2. Who was the first person to develop child analysis through play?

Q3. Who developed the Cattell Infant Intelligence Test Scale?

Q4. What do the following have in common?

Bender-Gestalt Test (Bender, 1938); Taylor Manifest Anxiety Scale (Taylor, 1953); Kent-Rosanoff Word Association Test (Kent & Rosanoff, 1910); Thematic Apperception Test (Morgan & Murray, 1935); Sentence Completion Method (Rohde, 1946).

Q5. The following are the last names of individuals who have contributed to the scientific study of human behavior. What else do these names have in common?

Ausubel, Bellak, Brunswick, Buhler, Dennis, Gardner, Gibson, Glueck, Harlow, Hartley, Hoffman, Horowitz, Jones, Kendler, Koch, Lacey, Luchins, Lynd, Murphy, Premack, Rossi, Sears, Sherif, Spence, Staats, Stendler, Whiting, Yarrow.

Now for the answers:

A1. Lois Murphy and Ruth Horowitz (1938).

A2. Hermine von Hug-Hellmuth (1921).

A3. Psyche Cattell (1947).

A4. A woman is either the senior author or the sole author of each work.

A5. They are the surnames of female social scientists.

When these questions were asked of an amicable male colleague, his response was to smile, shrug politely, and answer "That's nice—uh—so what?"

One answer to the question "So what?" can be found in an incident that occurred in the Cornell Psychology Department not so very long ago. Some psychology graduate students were concerned about departmental governance. They circulated a memo demanding that the faculty reevaluate departmental procedures. Included in the memo was the suggestion that the faculty revise its admission policies in light of the high proportion of women accepted for graduate study in psychology. "After all," it was pointed out, "women just drop out or go on to get married and waste their edu-

cation. Besides, what have women ever contributed to psychology, anyway?"

That graduate students at a prestigious Ivy League school would hold so little respect for the contributions of women to their chosen field demonstrates that the male orientation of psychology goes beyond discrimination in employment (Astin et al., 1972), bias in selection of subjects (Carlson, 1971; Schultz, 1969), overgeneralization of findings from males to all persons (Dan & Beekman, 1972), or the formulation of concepts and theories (Broverman et al., 1972; Chesler, 1972; Weisstein, 1968). Male bias pervades the very essence of the profession—the historical definition of the field of psychology itself.

In addition, the fact that two of the originators of the memo at Cornell were attending a seminar on perceptual development given by Eleanor Gibson shows that this sexist attitude will not be

¹ Requests for reprints should be sent to Nancy Felipe Russo, Department of Psychology, American University, Washington, D.C. 20016.

overcome by exposure to one or two famed "exceptions." Change will require a reorientation of the professional socialization process. Psychology must rediscover the contributions of its women and give them equal time and space with those of men.

The benefits of sensitizing psychologists to the contributions of women to the field are many. Two of the most important ones are provision of role models and service as a source of pride and inspiration. In addition, women's history can refute the stereotypes and myths that often form the foundation for discriminatory practices. If psychologists are taught to acknowledge, appreciate, and respect the contributions of women to the profession, their image of women cannot help but be altered, and behavioral change can thus be facilitated.

The lack of historical insight into the contributions of women psychologists is due to a multiplicity of causes, one of the simplest, and most insidious, being our method of documentation. In some publications only initials are used to indicate first names in bibliographies, while in others initials are used for men and women's names are spelled out in full. This inconsistency leads one to assume that the lack of a first name in a citation indicates that the work was done by a man. Unless they are directly involved in a research area, using original sources, psychologists are dependent on informal means (personal stories, anecdotes, etc.) to tell them that "X" was a woman. Confusion is increased when women marry and change their names, losing continuity of documentation. As the years increase between the time a woman first publishes her research and the current moment in time, there is a decrement in the likelihood that someone will be around who "remembers" that this work was done by a woman.

The tendency to cite research by referring only to surnames carries over to informal conversation. Many people, for example, know Freud (1946) first reported on the defense mechanism of intellectualization, but few realize that in that case Freud's first name was Anna. When there are two psychologists of the same name—one male, one female—and research is cited by use of the last name only, it is often assumed that the work referred to is that of the male. If we begin to discuss the work of the social psychologist, Sherif, for example, how many people think of Carolyn? What a shock it was to go through six years of studying perception and then to find out that Zeigarnik's first name was Bluma.

Without a commitment by the profession to historical research and consciousness raising, the early contributions of women to psychology will be lost. We will probably never know how much work was done by women but credited to men: how many footnotes of appreciation should rightfully have been coauthorship, how many times junior authorship should have been senior authorship, or how many times it was the male coauthor who should have received the footnote. But we can, at least, become sensitive to the contributions that we do have record of and develop a better appreciation of them. Perhaps the question "What have women ever contributed to psychology" would not have been asked at Cornell had the students been aware that it was at this very University that Titchener's first doctoral student, Margaret Floy Washburn (1908), put together a compendium of animal psychology, which not only became a classic in the field, but which provided a partial impetus for the development of behaviorism.

Once one starts looking, contributions of women are found everywhere. Indeed, it is a source of inspiration that despite the discrimination, the hardships, and the restrictions, so many women did so much. Yet their work is not given proper recognition. For instance, it is not generally known that the principal author of the Thematic Apperception Test was Christiana D. Morgan (Morgan & Murray, 1935), or that the current revision of the Stanford-Binet Intelligence Test was coauthored by a woman (Terman & Merrill, 1937). In a time when women are searching for role models and new identities, it is exciting to discover that Taylor of the Taylor Manifest Anxiety Scale is named Janet, that Bender of the Bender-Gestalt test is known as Lauretta, and that the Kent of the Kent-Rosanoff Word Association Test was called Grace.

Women's contributions to the theoretical development of psychology have had a major impact on the development of new fields of inquiry, both in psychology and in related social sciences. Nancy Bayley (1933) and Anne Anastasi (1937) are recognized leaders in the field of testing, but one must also acknowledge the efforts of lesser known persons such as Grace Fernald, who, with William Healy, did pioneer work with delinquent children, developing an early series of performance tests (Healy & Fernald, 1910). Grace Fernald is not to be confused with the experimental psychologist Mabel Fernald (1912), who is known for her classic work on imagery and memory.

In visual perception, Magdalena Vernon (1937) has been a major influence, and Mary Henle (1961) is a principal figure in Gestalt psychology. Melanie Klein (1948), Anna Freud (1946), and Karen Horney (1939) have each influenced new directions in psychoanalysis. While Mead (Margaret, not George) (1939) and Benedict (1934, 1938) are known for their central roles in the development of the new fields of culture and personality, and psychological anthropology, lesser known figures include Martha Wolfenstein (1950), Florence Kluckhohn (Kluckhohn & Strodtbeck, 1961), and Dorothea Leighton who coauthored two of the classic books in psychological anthropology with a prominent male anthropologist to whom these works are sometimes attributed (Kluckhohn & Leighton, 1946; Leighton & Kluckhohn, 1947). Also important (but neither last nor least) in these areas is Eggan (1949), who first suggested that dreams could be sources of valuable cross-cultural data.

In the field of social psychology, the studies of conformity are generally associated with the name of Asch, but a little-known woman (Berenda, 1950) was doing identical work at the same time. The group studies in cooperation and competition were first inspired by the work of a woman (Hurlock, 1927). The classic study on the authoritarian personality was the product of the central contributions of a woman (Adorno, Frenkel-Brunswick, Levinson, & Sanford, 1950; Frenkel-Brunswick, Levinson, & Sanford, 1948), as were the comprehensive works on the need for social approval (Strickland & Crowne, 1962) and Machiavellianism (Christie & Geis, 1958). Two women contributed to a classic experimental study of aggression (Bandura, Ross, & Ross, 1961), and the first successful test of a psychoanalytic concept was the work of yet another woman (Goldman-Eisler, 1953). As Rosenthal (1966) noted, one of the earliest works that led to the uncovering of the Rosenthal effect was that of Edith Lord (1950). Finally, it should be mentioned that a woman was responsible for the current revision of the code of ethics on experimentation with human subjects by the American Psychological Association (Baumrind, 1964).

Classic texts in all fields of psychology have been written by women, or contributed to by women as second authors, including the works of Arnold (1960), Anastasi (1937), Benedict (1934), Bruner, Goodnow, and Austin (1956), Buhler (1939), Goodenough (1945), Jahoda, Deutsch,

and Cook (1951), Maccoby, Newcomb, and Hartley (1958), Murphy (1937), Rickers-Ovsiankina (1960), Sherif and Sherif (1953), Shirley (1933), and Tyler (1956).

All psychologists are familiar with the Terman studies on genius, but not many know that two of the volumes presenting the results of those studies were written by women (Burks, Jensen, & Terman, 1930; Cox, 1926), or that John B. Watson's famous Albert experiment was coauthored with a woman (Watson & Rayner, 1920).

These examples are not just *curiosa*, nor are they meant to be comprehensive. They just represent the tip of a very large iceberg.

The current practice of using initials for all citations will only serve to obscure the contributions of women to the profession. As long as the English language uses pronouns of male and female gender so that we must say "she found this," or "he discovered that," psychologists must have a systematic means to designate the contributions of women to its journals. This is not incompatible with blind reviewing. Blind reviewing is essential so that females do not take to submitting articles with only their initials for fear of rejection due to prejudice. If such a practice became widespread, we would not even have the original sources to preserve the woman's identity. The contributions of contemporary women should not be lost. We need them as well.

Practices of discrimination and prejudice will not be overturned by adequate record keeping, however. Adequate documentation is a necessary, but certainly not a sufficient, means to upgrade the status of women in psychology. The professional socialization process itself must undergo a basic transformation.

The leadership of the American Psychological Association has recently been moving to assess and advance the position of women in the profession. The Task Force on the Status of Women in Psychology has done some very fine work toward these ends and has submitted a report which acknowledges the need for a professional reorientation. It recommends, among other things, that "appropriate subspecialties should inquire in depth into the psychology of women. New courses should be created to explore the psychology of women: e.g., developmental psychology of women, social psychology of women's status [Astin et al., 1972, p. 15]."

We affirm the exigency of such curriculum revision. However, psychologists must not limit

themselves to the study of the psychology of women—they must also study the women of psychology. Without historical insight, without an intellectual history (“herstory?”) women will never be truly integrated into the profession. The current approach seems to be “let us in.” We think the approach should be “recognize that we are here—and we have been here for quite a while. See what we’ve done despite adverse circumstances and incredible odds. Think of what we could do if we had an equal chance.”

So we say, “Up with our foremothers.” Teach women in psychology their intellectual history and preserve the contributions of contemporary women. Women have a proud tradition of accomplishment in the profession. Let it be recognized—by both women and men.

Contributions to Education in Psychology Awards

The American Psychological Foundation invites nominations for the 1974 Contributions to Education in Psychology award. The annual award is in the amount of \$1,000 to be given to the recipient for his achievements. It is hoped that the awardee's institution will contribute a matching sum, thus providing the recipient with a modest "grant" to be used by him as he wishes to "improve the teaching of psychology." Thus, the objective of the award program is to enhance the local instructional program, not just to recognize "master teachers." Because the awards are to be presented at the APA Annual Convention in September 1974, *nominations must be completed and sent to the Committee by March 31, 1974*. A nomination form with a statement of the guidelines and suggestions for documentation can be obtained by writing to Wilse B. Webb, Chairman, APF Teaching Awards Committee, Department of Psychology, University of Florida, Gainesville, Florida 32601.

New Members and Associates of the American Psychological Association

The Board of Directors announces that the following 2,906 persons were elected to initial membership in the American Psychological Association as of January 1, 1974. Of these, 1,929 were elected as Members, and 977 as Associate members. Though not all of them

have validated their election by payment of initial dues, all but a few will eventually do so.

In addition, in accordance with Article II, Section 8, of the Bylaws, 346 Associate members were transferred to Member status as of January 1, 1974.

Comment

Response to Rogers' "Challenges"

Carl Rogers' article in the May 1973 issue was very interesting. As the only professional radio broadcaster in the APA, over the 25 years that I have broadcast "Psychologically Speaking" I have tried continuously to interest the program chairmen of the national conferences to have some meetings on the public attitude toward psychologists: the public's general suspicion of the freakish demonstrations in psychologists' so-called "therapy" and some measure of control over the completely nonvalidated outpourings in psychology's so-called literature for the public. And consistently the bureaucracy has not even had sufficient interest to answer my mail. The culmination was at the San Francisco meeting where the balcony of the Fairmont Hotel was inhabited by such goings on in the name of "humanism" that even a modern insane asylum would have been ashamed of it.

What pains me most is to ask Rogers to remember back to when he started most of this. Whatever he might have felt was a "scientific" approach to "client-centered counseling," he started the movement of listening only and also the notion that all one had to know in "practising psychology" was to listen and that "advice" is a dirty word. But all of this is the psychologist's notion. The client is not at all interested in doing all the paying and all the talking. He would like some advice, but surely he will not receive it in weekend nude encounters, or encounter groups with bedrooms, or touch and squeeze the muscle groups, or publications that extoll the use of sex relations with the therapist. We, as a group, are so afraid that we will be criticized that we have

lost our identity with the community as a group that either sets standards or has any interest in them.

When I want a good book that discusses human problems, I choose one written by a layman rather than by a psychologist because the layman is interested in human problems. I am sorry to say that the least effective broadcasters on human problems are psychologists, who are chiefly interested in aggrandizing their reputations and purses.

May I suggest to Dr. Rogers that at the next annual conference he have a "symposium" of psychologists who meet the public. We are never represented. Why? I suspect that the members are afraid of what we will say.

Subject Cooperation in Experiments

At first glance the results of Resnick and Schwartz (February 1973) greatly disturbed us. The students in their experiment appeared to cooperate more under the "unethical" than under the "ethical" condition. This seemed to imply that undergraduate students will cooperate more with a relatively unethical professor or experimenter who behaves according to expectations than with an experimenter who is completely honest and open.

We feel that the effect of the independent variable (ethical behavior) in this experiment was badly confounded by length, complexity, and interest level of instructions. There was also possible confounding

by experimenter characteristics, for example, prestige, confidence, bias, and degree of professional "know how" conveyed by the experimenter. Furthermore, in order to shape trusting behavior, it will take more than telling people that psychologists will no longer practice deception.

We wonder if the concern for differences between the two ethical codes in this experiment does not mirror the conflict between the two philosophies coexisting in psychology and, in fact, in our society. One philosophy emphasizes total responsibility by authority, and the other places value on individual responsibility and decision making. In the first case, the experimenter is in control and gives the subject minimal information. In the second case, the experimenter shares his or her hypotheses and hence shares control with subjects. The latter experimenter encourages independent decision processes in subjects (students). These processes may of course lead the subject to resist the influence of experimenters (authority figures). Honesty on the part of both subject and experimenter seems feasible only under the latter condition. We agree with Resnick and Schwartz that the comparative "ecological validity" of these two systems or codes merits serious consideration.

Seattle, Washington

Editor's note. The Resnick and Schwartz article was based on an early

draft of the research ethics report. The final report is very different (see "Ethical Principles in the Conduct of Research with Human Participants," *American Psychologist*, 1973, 28, 27-30).

Is Violence Itself Necessarily Bad?

I must take issue with several points in John P. Murray's (June 1973) highly biased article on television and violence. First, the evidence which he cites consists almost entirely of experiments on children in highly artificial situations, the results of which are hard to generalize to real-life settings, and correlational studies of adults which allow for a variety of cause-effect interpretations. Even the so-called "crucial" study by Lefkowitz et al. (1972) did not examine or control for such crucial factors as the child's self-concept or self-esteem. Nor did Murray cite or explain any of the negative findings on this subject (e.g., Feshbach & Singer, 1971).

Second, the definitions of *aggression* and *violence* (and "antisocial" behavior) are so broad and arbitrary as to include arguing, pushing, breaking toys, pushing "hurt" buttons, and delinquency. Does this imply that it is always bad for children to argue? (If so, does this mean that it would be better for them to simply "follow orders" when others tell them to do something they disapprove of?) Is pushing necessarily bad, say, for example, if one has been pushed around by a bully whom adults will not discipline? Is violence itself necessarily bad, or is it important to identify the full context before making such a judgment? For example, what about the difference between the initiation of force and self-defense? Is there a moral difference between an Eisenhower and a Hitler or Stalin?

Third, the author fails to recognize the possibility that watching violent programs might have certain beneficial consequences. For example, could watching *The Untouchables* show a child that (a) there

is nothing romantic or admirable about being a criminal, (b) justice will be done to evildoers ("crime does not pay"), (c) the way to oppose evil is by a heroic, noncompromising attitude on the part of good men.

One gets the distinct impression from Murray's article, including his conclusion that television violence should be reduced, that his ideal child (or adult) would consist of a schmo: a being who wants nothing, will fight for nothing, including his own life or property, and will stand up for nothing regardless of the circumstances.

Supports Crisis Phone Services

With respect to Lester's (May 1973) criticisms that hotline telephone counseling is unsupervised, executed by poorly trained individuals, and potentially dangerous in that such agencies may violate professional ethics, I must take issue. This attitude toward paraprofessional efforts represents an elitism within the mental health field that posits nonacademically trained individuals as being unable to lend constructive support and help to other human beings. When a friend helps another friend, he is applauded. When caring individuals organize a service to help others in a crisis situation, a cry of impropriety is made by those professionals with power

in the field. In my opinion, this attitude and underlying assumption is both dangerous and fallacious: dangerous in maintaining a small professional elite, and fallacious in assuming that a PhD is necessarily more able to provide crisis "help" than a non-PhD.

In the face of such a shortage of manpower in the mental health field, such efforts must be supported. Training sessions for volunteers are necessary, but the demand for supervision by psychologists sounds more like a demand for control rather than a genuine offer to help paraprofessionals. Let us not forget that those who are trained, untrained, and in need of help make up part of the community who are both therapists and patients, really nothing more or less than people who want to help and who seek help. The ability to empathize, listen, offer suggestions, and simply to "be there" in a time of crisis are not "trainable" qualities, nor qualities that need "supervision" as Lester implies, but rather constitute the best of being human.

PAUL SCHOENFELD
California School of Professional Psychology

Lester Replies:

In reply to Schoenfeld's comment, there are several points worth making: (a) Schoenfeld implies that supervision of paraprofessionals is not necessary. By extension, then, are internships, supervision, licensing, and codes of ethics unnecessary for psychologists? (b) Schoenfeld equates supervision with control. I would equate it with both teaching and control. (c) Paraprofessionals do not act in the way that "friends" do. It is for this reason that selection and training are so critical for counselors of all kinds. (d) Those who have worked in crisis

services have experienced the results of lack of supervision. I have seen one counselor fall asleep while a client talked on the telephone to him. I have heard another respond by laughing when a client began a call by stating her suicidal intent. I have found counselors acting as therapists to clients after the counselors have left the crisis service. (e) We can no longer choose between control versus no control. The issue now is becoming "Who shall control?" It would be useful for the psychology profession if psychologists were given equal status with psychiatrists in the licensing of hotlines and crisis services.

What Constitutes a Social Good?

John Platt's (August 1973) article "Social Traps" was a clear exposition of a conceptual basis for applying behavior modification principles to social problems. Hidden, however, were assumptions on what constitutes a social good and the definition of long range, particularly as it implies an eventual locking-in of a system. Also ignored were the adverse side effects that might be generated by using devices he advocated, such as establishing a superordinate authority. Nor is there clear-cut evidence for some of the assertions he made. For example, he related how Indiana and Ohio, by setting up toll road corporations, converted short-range pay and return on investment, R_S^+ , to an eventual benefit, R_L^+ , that would accrue to the state and all the drivers. The odds are that had the toll roads not been built, the development of free interstates would not have been so impaired. Thus, because of threats to the revenues of the Indiana Toll

Road, it took over 10 years to complete a short leg of I-94 between Gary, Indiana, and the Michigan state line. In the meantime, motorists were forced to use two-lane, crowded, and dangerous state roads. The "long-range" benefits lasted only a few years, but the "long-range" punishments (tolls) will last another 10.

In Illinois, the Toll Road Commission appears to have an eternal life. Rather than pay off the bond issues as the profits accrue, a new sparsely used toll road is being built. Again, how long is "long"? Yet, toll roads do have a benefit for a minority segment of motorists in that the costs dissuade many who would otherwise contribute to its congestion. Hence, the long-range benefits do accrue to those willing and able to make the financial expenditure, but the concept also locks out those who are not. Are we then not discriminating against the poor?

Medicare is another example of mixed blessings. In the short range, the medical delivery system seems to have been strained, even though one major segment of our society appears to have greatly benefited. But in the long range, changes in the system induced by Medicare can have broader benefits.

Still another example is that many economists partly attribute the high costs of beef to the expanded welfare system whereby those formerly unable to purchase this item are now competing for scarce supplies. What are the positives and negatives to whom and for how long? And which social accountant is to determine these valences?

Did we lock in our television line-age standards too early, or should we have waited before standardizing, as Europeans have done? How much longer should we have waited to enjoy clearer color programs? No social venture, regardless of how noble the underlying philosophy, is devoid of adverse effect on some segments of the population nor is it "good" indefinitely. Similarly, none is "bad" indefinitely. Constant re-

adjustments in the social, political, and economic systems do take place, often alternating between "good" and "bad"; and this is the central problem, not arbitrarily specifying an oversimplistic long range without carefully examining the intricacies of the effects and the specific segments affected.

Other examples which Platt cited (e.g., Special Drawing Rights, European Common Market) are not clear-cut examples of social good. Neither did Platt explain why the demise of hundreds of leading newspapers over the past 20 years is necessarily bad or why media should not strive for higher audience ratings. (I am not even attempting to delve into the question as to whether violence depicted on television breeds violence.)

The technology of behavior modification, whether on an individual or a group basis, will probably constantly improve. But the major question is whether and what behavior should be modified, and the question must take into account not only the personal values of the technologist, but his awareness of the intricacies of the system and the balances between the "good" and "bad" at numerous points along the time scale.

Prefers Hardin's Solution

John Platt (August 1973) used Garrett Hardin's (1968) "The Tragedy of the Commons" as one example of the "social traps" with which he is concerned. After examining some suggestions for ways out of these traps, Platt suggested that a Skinnerian "reversal-of-reinforcers" approach is one that might help, and he added: "Some of these methods have been in use for hundreds or thousands of years, and much of our fashionable despair today comes

from a kind of willful blindness to the methods that society developed long ago [p. 648]."

Following this introduction to his suggestion of a solution he stated, simply,

the Tragedy of the Commons is essentially a problem of the allocation of scarce resources. And a half-hour's thought will turn up a dozen mechanisms that we use every day for dealing with such problems. [And] Hardin . . . made out his New England cattle owners to be a good deal more stupid than they actually were. The problem is not a problem of thoughtless competition, but rather the problem of setting up a superordinate authority to handle reinforcement mechanisms . . . for getting out of these traps [p. 648].

As one who found Garrett Hardin (and his New Englanders) neither stupid nor simplistic, I was troubled by Platt's characterization. Moreover, the problem with which Hardin was struggling seems not to be comprehended by Platt. Hardin's concern, and mine, is that of scarce resources in a free society. Platt's methods, those that have been in use for hundreds or thousands of years, may well be successful in dealing with a problem of the allocation of scarce resources. They are methods that have had the luxury of not dealing with a free people. Platt is right: Set up a superordinate authority. But that solution is one Hardin saw as incongruous with a free society.

Platt's presentation brings sharply to the fore a concern that many psychologist-libertarians have about consequences of the Skinnerian scientific approach to human problems. At times the problem of freedom is recognized by Skinnerians before it is discarded. In this case, however, Platt seems not to have seen the freedom issue, even though it was central in Hardin's thinking. And Platt's answer—a superordinate authority using our scientific knowledge and methods!—is frightening. I, for one, far prefer Hardin's social trap and his dilemma to Platt's help to a way out.

Recruitment of Minority Group Students and Women

This Comment describes recruitment efforts of fully approved APA doctoral programs in clinical psychology. More specifically, the study described herein attempted to determine how many programs actively recruited members of minority groups and women and, in addition, how the actual recruitment procedures were handled in the application materials.

In recent years, professionals in psychology have been recognizing that members of minority groups as well as women have been underutilized in psychology; there is little agreement, however, about how to rectify the imbalance. One approach is to maximize the number of applications sent in by members of minority groups and women so that there would be a wider base of qualified applicants from which to choose. If recruitment of more applications from minority group members and women is a potentially effective method of democratizing psychology, it is important that psychology departments be aware of what is the current status of recruitment and how various departments actually have recruited applicants.

Method

The list of fully approved APA programs in clinical psychology as of July 1, 1972, was obtained from the manual *Graduate Study in Psychology for 1973-74* (APA, 1972). Clinical psychology programs were chosen as a target group for two reasons: (a) the relatively large number which could yield potentially more data and (b) the recent concern of applied fields in psychology for diversifying the cultural composition of their students. Although the total number of programs was 69, 4 programs did not send their application materials. Consequently,

the total number of programs was adjusted to 65.

I sent to each program a brief letter which stated an intention to go to graduate school and a request for application materials. I felt such a deception was necessary because I was interested in analyzing recruitment procedures as they appeared in the regular application materials. I wanted to view the recruitment policies from the vantage point of an applicant, rather than from the vantage point of the program, for how the program views its policies may be quite different from how an applicant perceives the policies.

Next, the literature from each school was read, and those programs that attended to minority group members or to women were identified. Those programs recruiting were then rated on a 7-point recruitment continuum. The recruitment categories were the following: (1) statement of encouragement to apply; (2) statement of interest; (3) statement of the program's commitment to minority groups or women; (4) statement that scores, etc., are considered in the context of cultural background or special consideration given; (5) statement that a certain number of admission openings were available for minority members or women; (6) statement of cooperation with the Black Students' Association and/or the Association of Black Psychologists; and (7) statement of specific inducements, that is, fees waived, financial support, test scores optional.

The recruitment scale was not an interval scale, but rather a rough rank order of recruitment procedures that were ordered on the basis of an increasing amount of information offered to applicants about the program's commitment to minority group and women's admissions. For example, one sentence encouraging an applicant to apply did not seem as strong a message as did an offer of specific inducements to apply. However, the middle range became more interchangeable and it was possible to score on several categories. In addition, stating a commitment was scored only when the literature stated "commitment" or clearly indicated commitment with another choice of words. However, those programs which recruited in another form seemed to be illustrating some type of commitment in practice, and this should be taken into account when reviewing the results. Finally, statements of nondiscrimination were not considered recruitment.

Results

Two basic questions were of interest: (a) How many clinical psychol-

ogy programs recruited (according to the definition used here) minority group members and women, and (b) what were the various forms of recruitment?

Of the 69 clinical psychology programs, 65 schools responded to the letter by sending their application materials so that there was a 94.2% return rate. While 22 or 33.8% of the programs recruited members of minority groups, 2 programs or 3% recruited women. Consequently, 43 or 66% of the programs did not recruit minority group members and 63 or 96.9% did not recruit women.

The next point of interest concerned the various forms of recruitment chosen by the clinical psychology programs. Concerning the recruitment of minority group members, 15 of the 22 programs scored on the first half of the continuum. More specifically, 7 programs offered statements of encouragement, 4 stated interest, 4 stated their commitment to increasing the participation of minority group members, and 7 stated that special consideration would be given. The remaining 13 programs scored on the latter part of the continuum which involved stronger recruiting measures. Of those 13, 9 offered special inducements. The most frequent inducement which was used by 5 schools involved special financial support. Regarding the other inducements, 2 schools waived application fees and 2 schools stated that test scores were optional. Only 1 school told the applicant that a certain number of admission openings were available, while 3 schools indicated cooperation with the Black

Students' Association and the Association of Black Psychologists. Of the 22 schools, 9 scored on more than one category, with 4 schools using three different recruitment strategies.

Only 2 schools recruited women, and the form was one of encouragement to apply. One university wrote, "Women and minority groups are encouraged to apply for admission." Another school wrote, "We find that holders of the M.A. and M.S. who enter this department do well in graduate work here. Their applications, like those of women, and of members of minority groups, are especially welcome."

Discussion

The analysis of recruitment strategies had several limitations. First, the study did not measure the programs' intentions, but rather the written indicators of such intentions. In addition, application materials may not represent the actual quality of supportive relationships existing in any program. Consequently, the result cannot be construed to indicate actual practices of each clinical psychology program. Second, an element of personal judgment was necessarily involved when rating the forms of recruitment. However, there were only two cases when the author felt in some doubt.

It seems fairly clear from the results that the recruitment of minority groups and especially of women was not widely practiced. Of those programs that did recruit, many gave little information to the applicant about the program's stand on the

issue, the program's willingness to support a member of a minority group or a woman both emotionally or physically, and the program's understanding of why they want to increase applications from minority groups and women. In other words, many schools gave little reason for the applicant to take the recruitment seriously.

There was a noticeable lack of attention to the female applicant. One school informed applicants that the school provided many jobs for the wives of graduate students but did not mention job opportunities for husbands of graduate students. The current attempts to recruit women have not included the following potentially useful incentives: (a) special scholarships for women, (b) jobs for husbands, (c) day care, (d) part-time graduate study, and (e) study through correspondence.

The results of this study may encourage those responsible for admissions to clarify their position on the recruitment issue and to learn from the practices of other programs concerning the elements of a clear and strong recruitment strategy. At this time, the professional staff of clinical psychology programs seem ambivalent about recruitment of minority group members and women.

Announcements

1974 Regional Placement Activities

You are invited to use the placement services at the regional psychological association conventions this spring. Employers who wish to attend or to list positions with any individual regional convention must contact the appropriate placement official listed below. In addition, APA will publish the *APA Regional Placement Bulletin* (positions only) for distribution at the regional conventions. This provides a single source of information that is available at all seven meetings, as well as through APA. It does not take the place of registering with any of the individual Placement Offices. Employers thus have two options:

1. Listing in the *APA Regional Placement Bulletin*, distributed to all seven regional conventions (\$5 fee required for each printed listing—**SEE MUST ACCOMPANY COPY**). *Deadline: March 22, 1974.*

2. Separate and/or additional listings at any of the seven regional conventions (check local Placement Chair as to individual fee requirements).

Southern Society for Philosophy and Psychology: April 11-13, 1974; International Inn, 4800 W. Kennedy Boulevard, Tampa, Florida. *Placement Chair:* L. B. Cebik, Department of Philosophy and Religion, University of Georgia, Athens, Georgia 30601.

Eastern Psychological Association: April 18-20, 1974; Sheraton Philadelphia Hotel, Philadelphia. *Placement Co-chair:* Joseph DuCette and Emil Soucar, Department of Educational Psychology, Temple University, Philadelphia, Pennsylvania 19122.

Western Psychological Association: April 25-28, 1974; Sheraton-Palace Hotel, San Francisco, California. *Placement Chair:* Judi Komaki, Psychology Department, San Jose State University, San Jose, California 95114

Southeastern Psychological Association: May 2-4, 1974; Diplomat Hotel, Hollywood, Florida. *Placement Chair:* Michael Epstein, University of Miami, Box 8185, Coral Gables, Florida 33124.

Southwestern Psychological Association: May 2-4, 1974; Paso del Norte Hotel, El Paso, Texas. *Placement Chair:* Paul Whitmore, HumRRO Division 5, Post Office Box 6057, Fort Bliss, Texas 79916.

Midwestern Psychological Association: May 2-4, 1974; Conrad Hilton Hotel, Chicago, Illinois. *Placement Chair:* David W. Bortree, Box 476, South Holland, Illinois 60473.

Rocky Mountain Psychological Association: May 8-11, 1974; Cosmopolitan Hotel, 18th and Broadway, Denver, Colorado. *Placement Chair:* John Hocking, Veterans Administration Hospital, Mental Hygiene Clinic, 1055 Clermont Street, Denver, Colorado 80220.

Applicant and general inquiries about placement facilities should be directed to the convention officials whose names and addresses are listed above.

Please note the first regional convention is April 11, necessitating the *APA Regional Placement Bulletin* closing date of March 22 (earlier announcement to employers was made by letter and the January, February, and March *APA Employment Bulletin*).

The printed *APA Regional Placement Bulletin* will be available at the conventions for \$1.00 per copy, or may be ordered by mail (available April 2) by sending \$1.50 to Regional Conventions, Placement Services, American Psychological Association, 1200 17th Street, N.W., Washington, D.C. 20036.

American Board of Professional Psychology

The American Board of Professional Psychology, during the period September 12-December 12, 1973, awarded its diploma in the special-

ties of Clinical and Industrial and Organizational Psychology to the following:

CLINICAL

Rose E. Boyarsky
Allen Mark Feinberg
Lane Anthony Gerber
Mack Raymond Hicks
Floyd S. Irvin
Paul Kessel
Theodore Landsman
Joel Morton Liebowitz
Shirley Sanders
Bruce T. Saunders
Freda Beth Stone
Robert H. Woody

INDUSTRIAL AND ORGANIZATIONAL

Ronald O. Lippitt

Corrections

In the listing of the Industrial Psychology II paper session on page 825 (September), the affiliation for Stephen L. Cohen is incorrect. His correct affiliation is University of South Florida.

In the ABPP diplomate listing on page 1017 (November), Jefferson M. Fish is incorrectly listed as Morris Jefferson Fish.

Two names were inadvertently omitted from the list of 1973 consultants for the *American Psychologist* on page 1136 (December). They are D. James Dooling and Robert Perloff. Their contributions are greatly appreciated.

In the first Comment in the January issue ("Some Comments on Hersch," pp. 54-55), the second author's name was omitted. He is Leslie G. Brody of the Indiana Department of Mental Health. We regret the error.

Fellowships; Predoctoral and Postdoctoral Programs

Leadership Program in Community Mental Health, School of Public Health, University of California, Berkeley: Now accepting applications for 1974-1975 academic year. An interdisciplinary curriculum providing skills in planning, administration, consultation, community organization, and research is integrated with innovative field experience. Requirements are a master's degree in a mental health related field and suitable work experience. An MPH is awarded after one year of study. Some stipends available. *Final application deadline is March 1, 1974.* For further information write to Robert Z. Apte, School of Public Health, Earl Warren Hall, University of California, Berkeley, California 94720.

Division of Psychology in the Department of Psychiatry at the Neuropsychiatric Institute of the University of Illinois: Now accepting applications for postdoctoral fellowships in community psychology. The program is planned to enable students to spend a year with the supervision and instruction of experts in the field. They will be developing specialized knowledge and skills for organization, planning, execution, and evaluation of community mental health programs. Through seminars and supervised field experience, the fellow is exposed to such areas as community organization, epidemiology, and ecology. Specialized training is also given in the techniques of community organization, consultation, and crisis intervention. Trainees will be selected with backgrounds in social and clinical psychology. The stipend is \$9,240 per year. To apply or obtain further information write to Wade H. Silverman, Community Psychology Program, Psychology Division,

Child Psychology Section of the University of Iowa Psychopathic Hospital: Now offering a postdoctoral fellowship in child-clinical research, consultation, and service. Applicants whose degrees are in clinical, developmental, experimental, school psychology, or related fields will be considered. Appointments are for one year, beginning no later than October 1, 1974, with a possible second year. First-year stipend: \$10,500 (taxable). Send letter of application and curriculum vitae to Jan Loney, Department of Psychiatry, College of Medicine, 500 Newton Road, Iowa City, Iowa 52240.

Division of Pediatric Psychology, University of Maryland School of Medicine: Now accepting applications for 1974-1975 internships in clinical child psychology presenting comprehensive field training in clinical child, pediatric psychology, and developmental disabilities. The program has an interdisciplinary focus, and there is close association with the Department of Child and Adolescent Psychiatry. Applicants with background in clinical, counseling, and school psychology considered. *Deadline for completed application is March 11, 1974.* For more detailed information write to Thomas Kenny or Rudolph Bauer, Division of Pediatric Psychology, University of Maryland Hospital, Baltimore, Maryland 21201.

College of Law and the Psychology Department of the University of Nebraska-Lincoln: Announce the law-psychology graduate studies program leading to both a regular law degree, the Juris Doctor, and a PhD in psychology. This program will typically take a student five years to complete both degrees. The student may take his PhD in any of four areas: general-experimental, social-personality, community-clinical, or psycholegal studies. For further

Psychiatric Associates of Tidewater, Inc.: Now accepting applications for predoctoral internships in clinical psychology to commence either June or September 1974. The internship is a rotating one and will offer opportunity for intensely supervised experiences in psychological assessment, individual and group psychotherapy with children, adolescents, and/or adults. Interns will be required to participate in group training experiences with residents in psychology as well as in individual supervision. Rotation will be through outpatient and inpatient facilities as well as through child-adolescent and adult services. The group is interdisciplinary and each intern will have an opportunity to associate with and learn from social workers and psychiatrists as well as psychologists. Application is rather informal and should be accompanied by a vita, a transcript, and recommendations. Stipend is \$7,000. Applications should be made to Joseph D. Warner, 500 Wainwright Building, Norfolk, Virginia 23510.

University of Wisconsin Center for Health Sciences: Postdoctoral fellowship in clinical neuropsychology. Two-year postdoctoral training program with emphasis on neuropsychological assessment of children and adults with known or suspected CNS dysfunction, and research in brain-behavior relationships, including application of biofeedback and conditioning techniques to neurological patients. Applicants must have PhD in psychology. Stipend: \$8,000 for 11 months, \$3,600 of which is tax exempt. Applications for September 1974 now being accepted; *deadline is May 1, 1974.* For additional information write to Charles G. Matthews, Neuropsychology Laboratory, Department of Neurology, University of Wisconsin Center for Health Sciences, Madison, Wisconsin 53706.

Sprinthall & Sprinthall isn't really a book.

It's a wide-angle lens.

Richard C. Sprinthall and Norman A. Sprinthall designed this remarkable lens. They call it **EDUCATIONAL PSYCHOLOGY: A DEVELOPMENTAL APPROACH**.

It's a lens that comprehensively surveys the ed psych landscape. Where ed psych came from. Where it is. Where it can go. It puts the pieces together and makes them workable.

The focal point is the student. His physical, cognitive, emotional and moral development. From birth through adolescence.

In the background and interwoven throughout the scene are major figures, capsuled in a series of vignettes. They

summarize a textual maincurrent, pull together ideas and methods via a single personality. Freud, Bruner, Skinner, Piaget

and others.

It's a visual experience. Made cogent by the Sprinthalls' writing style. Lucid. Comfortable. Often entertaining.

One who scrutinized it had this to say: "If the book were published tomorrow, I would use it the very next time I taught educational psychology. It is the best all-round book I know of."

We agree, of course. Although we really think it's more like a lens.

ISSUES IN SOCIAL ECOLOGY **Human Milieus**

Rudolf H. Moos and Paul M. Insel, editors, Stanford University

"The book will certainly be widely accepted as a judicious and interesting reader in social ecology." —Kenneth H. Craik, University of California, Berkeley. "The content of the articles is the best I've encountered in any book of readings appropriate for a contemporary course in human ecology. The interdisciplinary nature adds useful diversity . . . topical, stimulating, and readable." —Patrick C. Jobes, Montana State University. Three weeks after publication, 14 colleges had already adopted **ISSUES IN SOCIAL ECOLOGY** for courses.

1974 616 pages \$7.95 paperback

THREE WORLDS OF THERAPY

Anthony Barton, Duquesne University

In **THREE WORLDS OF THERAPY** Barton vividly and concretely describes the three forms of psychotherapy espoused by Freud, Jung and Rogers and demonstrates how each is a plausible method of transforming people. To illustrate how each method works, and how each differs from the others, Barton takes a patient, "Mary," through each of the methods and she is cured three times . . . differently. A lively, readable introduction to psychotherapy and to abnormal psychology.

1974 ca. 270 pages paper

HUMAN SEXUALITY **Contemporary Perspectives**

Eleanor S. Morrison and Vera Borosage, editors, Michigan State University

Adopted at over 60 schools in its first 6 months! Deliberately thought-provoking, this book places primary emphasis on the psycho-sociological aspects of human sexuality. "Excellent . . . succinctly captures and effectively treats most of the critical areas and contemporary issues on the subject . . . a wonderful cross-section of articles." —Howard Lempert, State University of New York, Stonybrook.

1973 431 pages \$5.95 paper

IT'S ALL IN YOUR MIND **Understanding Psychology**

Kent Dallett, University of California, Los Angeles

For introductory psychology courses (and some advanced ones too). Quotes from users: "A small and very wise book which relates to students, causing them to think about psychology's most fundamental and enduring problems." "An ideal antidote to the many fact-laden texts." "An important and courageous attempt to talk sense about the unspeakable." "For those students who are hungrier for ideas than for grades."

1973 244 pages \$4.95 paper

*Joseph Luft's **Group Processes: An Introduction to Group Dynamics, and Of Human Interaction.**

DAVID C. RIMM, Southern Illinois University
JOHN C. MASTERS, University of Minnesota

BEHAVIOR THERAPY: TECHNIQUES AND EMPIRICAL FINDINGS

Practical application is the goal of this comprehensive presentation of behavior therapy techniques. It explains the basic theories and demonstrates how the relative beginner might apply procedures in different contexts.

The authors introduce therapeutic procedures without assuming significant

prior knowledge on the part of the student. They make effective use of case histories and controlled experiments as they cover techniques which include desensitization modeling, assertive training, operant procedures, aversive conditioning, self-control, and cognitive behavior therapy techniques.

CONTENTS:

The Nature of Behavior Therapy
Systematic Desensitization
Assertive Training
Modeling Procedures
Contingency Management

Contingency Management in Institutional Settings
Operant Methods in Self-Control
Extinction Procedures
Aversive Control
Cognitive Methods

465 pages \$10.95 probable price Ready April 1974

DONALD H. KAUSLER, University of Missouri

PSYCHOLOGY OF VERBAL LEARNING AND MEMORY

Primary focus is on verbal learning qua learning. Specific topics reviewed are organized in terms of the traditional tasks of verbal learning: paired associate learning, serial anticipation learning, serial recall, free recall and recognition learning. Each topic is supported by a systematic, critical analysis of the underlying processes.

To acquaint the student with the broader scope of the topic, the author incorporates a review of the historical development of theoretical and empirical issues as well as analysis of these issues from the perspectives of both S-R and information processing theoretical models.

CONTENTS:

Models of Verbal Learning
Attributes of Linguistic Elements
Paired-Associate Learning—Stage Analysis
Paired-Associate Learning—Extensions to "Higher-Order" Tasks
Paired-Associate Learning—Transfer and Retention Effects

Serial Learning—S-R Analysis; Serial Anticipation Learning
Serial Learning—Serial Recall; Connected Discourse
Free Recall—General Characteristics
Free Recall—Theoretical Issues
Recognition Learning

568 pages \$12.95 probable price Ready March 1974

Psychology Textbooks

MICHAEL S. GAZZANIGA, New York University

FUNDAMENTALS OF PSYCHOLOGY: AN INTRODUCTION

Professor Gazzaniga covers the topic spectrum from neurology to personality using the nature/nurture issue as the unifying theme. Creative use of case histories and specially commissioned il-

lustrations maintain a high level of motivation while the well-organized presentation keeps the material thoroughly accessible to the student. **A test-item file is available on request.**

CONTENTS:

Nature of the Organism
Developmental Processes
Measuring Behavior
Sensation and Perception

The Changing Organism
Personality and Social Behavior in Perspective
The Mind of Man

634 pages \$10.95

Ready in February

RICHARD J. KOPPENAAL, New York University

Unit Workbook for FUNDAMENTALS OF PSYCHOLOGY

Complementing this uniquely student-oriented text, Professor Koppenaal's **Unit Workbook** consists entirely of material class-tested at New York University. Based on the Keller plan, the **Workbook** permits the student to progress at his

own rate. He can evaluate his progress by using the four short answer tests that are provided for each unit. This combination of text and workbook is easily the most widely useful teaching resource available to any instructor.

180 pages \$2.95 probable price

PETER H. LINDSAY and

DONALD A. NORMAN, both at the University of California, San Diego

HUMAN INFORMATION PROCESSING: AN INTRODUCTION TO PSYCHOLOGY

An introductory text that brings the excitement of modern experimental psychology to the beginning student by side-stepping traditional presentation and getting him actively involved with the problems encountered in the examination of human perception, memory, and cognition. Their method is unorthodox; their success

is extraordinary. **Human Information Processing** is now widely used in freshman courses as well as more advanced courses including sensation and perception, cognitive processes, and experimental psychology. **A test item file and an instructor's manual are both available on request.**

CONTENTS:

Human Perception
Neural Information Processing
Theories of Pattern Recognition
The Visual System
The Dimensions of Vision
The Auditory System

The Dimensions of Sound
Neural Basis of Memory
Transient Memories
The Structure of Memory
Memory Processes
Language

Learning and Cognitive Development
Problem Solving
Decision Making
Decisions in a Social Context
Motivation

H & W

THE STUDY OF TEACHING

by Michael Dunkin, Macquarie University,
and Bruce J. Biddle, University of Missouri

The first comprehensive text on classroom behavior based on research evidence. **THE STUDY OF TEACHING** provides an integrated overview of concepts and procedures on classroom interaction. The book summarizes and analyzes empirically-based knowledge about teaching and the classroom environment that has been gathered over the past twenty years, and it provides an examination of concepts and procedures that is meaningful and practical for future teachers.

April 1974 480 pages
ISBN # 0-03-088499-8 Cloth \$9.95 (Tent.)

MULTIPLE REGRESSION IN BEHAVIORAL RESEARCH

by Fred N. Kerlinger and Elazar J.
Pedhazur both of New York University

Multiple regression is presented in this text as a general method for handling behavioral science data. Departing from the conventional separation of analysis of variance and regression analysis, the book demonstrates that the uniform approach of regression is more meaningful for the conceptualization as well as the analysis of research problems in the behavioral sciences. Application is emphasized; research studies are reviewed; computer usage is stressed.

1973 534 pages
ISBN # 0-03-86211-6 Cloth \$13.95

TEACHER-STUDENT RELATION- SHIPS: Causes and Consequences

by Jere E. Brophy, University of Texas and
Thomas L. Good, University of Missouri

Research on student individual differences which shape teacher attitudes and expectations is reviewed and integrated in this book. The authors emphasize that these attitudes, once formed, can affect classroom interaction patterns and lead to self-fulfilling prophecy effects. Stressing field research and its applications rather than laboratory studies, the book provides the most recent and comprehensive treatment available on expectations, attitudes and sex as they affect teacher-student interaction.

February 1974 416 pages
ISBN # 0-03-085749-x Paper \$5.95 (Tent.)

THE ESSENTIALS OF FACTOR ANALYSIS

by Dennis Child, University of Bradford

Students, teachers and researchers with a limited mathematical background who read professional literature in which factor analysis is used will welcome this book. It provides just enough knowledge of the method to help them understand the material. The text uses geometric rather than algebraic models to explain the process of factor analysis. Statistical knowledge beyond correlations, means, standard deviations, and z scores is not necessary.

1970 110 pages
ISBN # 03-9100075-8 Paper \$4.95

MEASUREMENT AND EVALUATION IN EDUCATION AND PSYCHOLOGY

by William A. Mehrens and Irvin J.
Lehmann, both of Michigan State
University

This basic text is designed to educate prospective teachers concerning the construction, evaluation, interpretation, and uses of teacher-made tests and standardized measurement instruments. Included are extensive discussions of topics such as criterion referenced testing and accountability. The book requires no previous knowledge of statistics. An Instructor's Manual is available by Charles Eberly

1973 673 pages
ISBN # 0-03-086323-6 Cloth \$10.95

STUDIES OF CHILD LANGUAGE DEVELOPMENT

by Charles A. Ferguson,
Stanford University and Dan I. Slobin,
University of California, Berkeley

A compendium of empirical evidence available is collected in this volume on the child's acquisition of language. The research covers the major areas of developmental psycholinguistics and presents findings on the acquisition of thirteen different native languages. The book presents both an historical overview of developmental psycholinguistics and a very current, up-to-date view of the field in a cross-cultural and cross-linguistic perspective.

1973 675 pages
ISBN # 0-03-077450-0 Cloth \$11.95

CHARLES C THOMAS • PUBLISHER

SEX CHANGE: The Achievement of Gender Identity by Feminized Transsexuals by Thomas Kando, *Univ. of California, Riverside*. A description of the postoperative adjustment in seventeen feminized transsexuals. Unlike the medical literature on transsexualism, this study examines the social relations of those who have already undergone the sex change. '73, 172 pp., 12 tables, \$7.50

THE MYTH OF THE GOLDEN YEARS: A Socio-Environmental Theory of Aging by Jaber F. Gubrium, *Marquette Univ.* Limited to a particular and newly-constructed approach to the social behavior of the aged, the socio-environmental theory, it is a systematic exploration of some issues of old age and aging, not a survey of them. The socio-environmental approach is an attempt to integrate and evaluate the mass of data about the elderly and the various practices used by practioners and professionals in dealing with them. '73, 244 pp., 5 il., cloth-\$9.75, paper-\$6.75

SLEEP RESEARCH: A Critical Review by Frank R. Freemon, *Vanderbilt Univ., Nashville*. A collection of the literature and research from the many disciplines examining the surprisingly complex behavior, sleep. The author, deleting unnecessary jargon, reviews the greater part of the field of research, criticizing certain experimental approaches, identifying important findings, and bringing the research together so that its results can be incorporated into other sciences. '72, 220 pp., 17 il., 14 tables, \$14.50

ECOLOGY AND THE QUALITY OF LIFE. Edited by Sylvan J. Kaplan, *Chevy Chase, Md.*, and Evelyn Kivy-Rosenberg, *Jersey City State College, Jersey City*. (24 Contributors) Based on the idea that any quality of life and every human being's relationship to the environment is a function of population growth and distribution, the availability of natural resources, and the multiplicity of viewpoints as the planet gets smaller. '73, 308 pp., 23 il., 11 tables, \$17.50

SEDUCTION: A Conceptual Model in the Drug Dependencies and Other Contagious Ills (2nd Ptg.) by Paul H. Blachly, *Univ. of Oregon, Portland*. An examination of self-destructive behaviors. Drug abuse is the model used, but promiscuity, gambling, delinquency, homosexuality, prostitution, illegitimacy, rioting, alcoholism and risk-taking activities frequently co-exist in the seduction-prone individual. Factors influencing the seduction threshold are discussed in detail. '73, 96 pp., 15 il., 11 tables, \$7.00

RELIGIOUS SYSTEMS AND PSYCHOTHERAPY. Edited by Richard H. Cox, a medical-consulting psychologist and clergyman. Foreword by E. Mansell Pattison. (40 Contributors) The three major sections of the book include discussions, from the psychotherapeutic and mental health point of view, of the world's fourteen major religious systems; indigenous and emergent systems such as magic, exorcism and witchcraft; and multiple systems with areas of concern to students of human behavior. '73, 520 pp. (6 3/4 x 9 3/4), \$19.75

Use good psychology on your students.

INTRODUCTION TO PSYCHOLOGY

Third Edition

New Impression

Normal L. Munn, University of Adelaide;
L. Dodge Fernald, Harvard University; and Peter
S. Fernald, University of New Hampshire

The New Impression of **INTRODUCTION TO PSYCHOLOGY** still has everything that made the Third Edition a leader in the field. It just has more of what many people liked best. There are sixty-five new "response papers" — extracts from spontaneous and lively student comments on basic psychological concepts. There are fifty-six additional photographs that explain textual material and make an outstanding graphics program even more outstanding. And, *Using Tests in Teaching*, the new evaluation manual, has over 1200 new test items — multiple choice questions with both single and multiple answers, as well as matching items. In addition, there is a special section on the Personalized System of Instruction for the Introductory Psychology course.

The Third Edition was good psychology. The New Impression is even better.

INTRODUCTION TO PSYCHOLOGY

Third Edition

New Impression

736 pages, 1974. Accompanied by Student Guidebook, Instructor's Manual, and Using Tests in Teaching. Available for examination now.

If you like everything about **INTRODUCTION TO PSYCHOLOGY** except its length, it is available in a shorter version:

PERSONALITY: Strategies for the Study of Man, Revised Edition

ROBERT M. LIEBERT, *State University of New York-Stony Brook*, and MICHAEL D. SPIEGLER, *University of Texas*

Updated text acquaints the undergraduate majoring in psychology with important theoretical and research issues in the field. Instructor's Manual available to adopters.
Spring 1974

STUDIES IN PERSONNEL AND INDUSTRIAL PSYCHOLOGY, Third Edition

EDWIN A. FLEISHMAN, *American Institutes for Research-Washington, D.C.*, and ALAN R. BASS, *Wayne State University*

Retains a balanced coverage of the field of industrial psychology, while stressing more recent and socially relevant issues of concern to the field. Examples of topics covered which are new to this edition include assessment centers, training of hard-core unemployed, discrimination in employment testing, organizational development, and the four-day work week. Includes supplementary references and a selective bibliography of suggested additional readings for the student's use. Paperbound

From THE FREE PRESS

THE DENIAL OF DEATH

Ernest Becker, Simon Fraser University

"A magnificent psychophilosophical synthesis which ranks among the truly important books of the year ... moves unflinchingly toward a masterful articulation of the limitations of psychoanalysis and of reason itself in helping man transcend his conflict-

ing fears of both life and death.... His book will be acknowledged as a major work."

THE PRESENT OF THINGS FUTURE: Explorations of Time in Human Experience

Thomas J. Cottle, Children's Defense Fund, and Stephen L. Klineberg, Rice University

The striking use of a quartet of fascinating and well-developed "life studies"—studies of four unusually perceptive individuals who speak with extraordinary insights of their encounters with time—enhance this

exploration of the psychological, sociological, and cultural forces that shape our perspectives on time.

1974

290 pages

\$8.95

HANDBOOK OF LEADERSHIP

Ralph M. Stogdill, Ohio State University

Based on more than 3,000 books and articles, this comprehensive reference volume abstracts, surveys, and analyzes all the published literature on leadership. In Stogdill's words, it is a sourcebook "intended for the serious reader who wants to know

what results have been obtained, who did the research, and what conclusions can be drawn from the accumulated evidence."

THE NATURE OF HUMAN VALUES

Milton Rokeach, Washington State University

A highly provocative and original work in social psychology, this volume describes what human values are, how they can be measured, where they come from, what they do, under what conditions

they change, and what effects changing values have on other kinds of change—especially behavioral change.

1973

448 pages

MESSAGES OF THE BODY

John P. Spiegel, Brandeis University, and
Pavel Machotka, University of California, Santa Cruz

Clinical studies, recent research, and literature from the sciences and humanities are reviewed and brought together to provide a new strong cognitive theory of body messages which is then tested by experiments. Profusely illustrated, this book pro-

vides not only a broad novel approach to the field, but also presents concepts and methods that will stimulate new experiments and applications of knowledge in the area of nonverbal communication.

Perspectives in Abnormal Behavior

Pergamon General Psychology Series, Volume 37

Edited by Richard J. Morris, Syracuse University, Syracuse, New York

An overview of the various perspectives currently found in the field of abnormal psychology which consistently stresses an interdisciplinary approach to the development and maintenance of abnormal behavior. Six major content areas are emphasized and include: problems in the identification of abnormal behavior; drug usage and alcoholism; factors related to the development of abnormal behavior; treatment perspectives; approaches to prevention; and issues regarding societal reactions to abnormal behavior. Introductions at the beginning of each unit will provide the student with a summary of the articles presented and give a general insight into the area of discussion. This material will be of special value to students and professionals in all areas of abnormal psychology, psychopathology and psychiatry, as well as graduate students in clinical psychology, counselling psychology, social work, and psychiatric nursing.

Journal Of Computers And Human Concern

Editor: T.D. Sterling: Simon Fraser University, Canada

Associate Editor: S. Pollack, Washington University, Seattle, Washington

A complete list of international editors available upon request.

The JOURNAL OF COMPUTERS AND HUMAN CONCERN will offer a means by which thoughtful and concerned persons can report and examine the human effects engendered by the computerization of civilization.

This Journal will act as a reporter, analyst, commentator, and as a medium of exchange and interaction. It will contain factual reports, in the tradition of scientific and critical investigation. The articles will describe accomplishments which used a computer as a creative medium and present evidence of the effects of computerization on human lives.

The editors at times will solicit comments from leading protagonists as special contributions. COMPUTERS AND HUMAN CONCERN will also publish information pertaining to meetings and new developments in the field. It will carry a *Letters and Comments* section; a *Work - New and in Progress* section; and an area on *Analysis and Criticism* as well as a featured section entitled *Commentary*.

We invite you to subscribe to this new and important Journal in the field of COMPUTERS AND HUMAN CONCERN.

Published Quarterly: One Year (1974) \$50.00; Two Years (1974-75) \$90.00

HEALTHY PERSONALITY:

An Approach From the Viewpoint of Humanistic Psychology

Sidney M. Jourard, University of Florida

Written by one of the leading contemporary humanistic psychologists, this book is both a revision of *Personal Adjustment* and a major new contribution to the study of personality. Its aim is to present the factors which influence personal growth and show how the barriers to well-being can be overcome.

The first chapter develops a concept of healthy personality based upon research and theory. Following this, a wide spectrum of personality variables—ranging from consciousness and emotions to religion and work—is examined in relation to this concept of healthy personality. In each case, the focus is on man's capacity for growth, as the book pinpoints those aspects of psychology that foster or limit growth.

1974 approx. 480 pages \$7.95

HUMAN DEVELOPMENT

A Multidisciplinary Approach to the Psychology of Individual Growth

James O. Lugo and Gerald L. Hershey, both, Fullerton Junior College

The *only* human development text with a dynamic, four-fold approach:

- *Inclusive*—presenting the entire human life cycle from before conception through old age, with special emphasis on childhood.
- *Multidisciplinary*—bringing methods and techniques of many fields into consideration in order to provide a basis for understanding human development and behavior.
- *Humanistic*—presenting viable life goals and values to strive for and live by.
- *Holistic*—studying the individual and his development from psychological, biological, and sociological viewpoints.

1974 approx. 704 pages prob. \$9.95

Psychology Books

PERSONALITY: A Behavioral Approach Second Edition

Robert W. Lundin, The University of the South

Continues to approach the psychology of personality from an experimental position. The new edition draws heavily on *human* behavior with updated references and new examples of behavior modification techniques. Chapters include learning theory, normal and abnormal development, and therapeutic techniques.

1974 approx. 480 pages prob. \$8.95

THEORIES OF PERSONALITY

William B. Arndt, Jr., University of Missouri—Kansas City

A major new text that presents the views of 17 of the world's most prominent personality theorists organized around 12 key conceptual issues. A special theorist index is included for instructors who wish to follow a more traditional approach. There are numerous examples and illustrations of the concepts discussed, and summary tables present the material in chart form. More than 1,000 book and page citations make this one of the best documented reference-texts available.

1974 approx. 500 pages \$10.95

THE STUDY OF ABNORMAL BEHAVIOR

Selected Readings Third Edition

Melvin Zax, University of Rochester; and George Stricker, Adelphi University

A well balanced collection of research literature and theoretical papers. Roughly 60 percent new material includes such articles as "On Being Sane in Insane Places" by D.L. Rosenhan; "The Use of Biofeedback Training in Enabling Patients to Control Autonomic Functions" by B.T. Engel *et al.*; and "The Hyperactive Child"—Philadelphia: Smith, Kline, and French Laboratories.

1974 approx. 481 pages paper \$5.95

PSYCHOLOGICAL TESTING Third Edition

Anne Anastasi, Fordham University

This extremely popular text presents information that enables students to evaluate psychological tests of any type, and to interpret the results correctly. Included are three appendices: a complete copy of *Ethical Standards of Psychologists*, a list of major test publishers which provide test catalogs, and a classified list of 230 tests.

NEW titles from Rand McNally

social psychology: classic and contemporary integrations

Charlan Nemeth, University of Virginia / This new paperback text introduces students to social psychology through a systematic study of its main problem areas. Each chapter is a creative integration of the available literature on a particular phenomenon, coupled with original insights by authorities in the subject area. Major theories are first subjected to empirical data and then modified where necessary to present a coherent picture of what is known and to demonstrate the process of scientific inquiry.

"If your students seem like conscientious objectors in the battle of learning, Nemeth can bail you out. The provocative scholarship collected in this book should create an appreciation for social psychology like nothing you've ever seen. Share this book, don't hoard it."

Karl E. Weick / Cornell University

c. 300 pages, \$5.95 Paper, \$8.95 Cloth

introduction to personality

Desmond S. Cartwright, University of Colorado / Bridging the gap between introductory psychology and advanced research, this new text clarifies and examines the important theories, methods, and research topics in personality. In each chapter, Professor Cartwright objectively describes an author's work or an area of research and then follows with a brief commentary. c. 600 pages, \$10.95 Cloth / Instructor's Manual

psychology of personality: readings in personality theory / 2nd edition

Edited by **William S. Sahakian**, Suffolk University / In over 20 articles by major theorists, this book presents the essential elements of classic works in personality. The new edition has added articles by Skinner, Binswanger, Boss, Frankl, and May. c. 600 pages, \$7.50 Paper

introductory psychology: a mastery coursebook

Walter M. Vernon, Illinois State University / Based on the mastery approach, *Introductory Psychology* combines workbook with core text. Interspersed throughout are rehearsal questions which focus on key elements and test a student's understanding of concepts. The questions have been carefully developed to relate directly to the content of the text. c. 400 pages, \$7.95 Paper / Instructor's Manual

Introductory psychology through science fiction

Edited by **Harvey A. Katz**, Suffolk University; **Patricia Warrick**, University of Wisconsin; **Martin H. Greenberg**, Florida International University / For a refreshing change of pace, this new reader dramatizes basic concepts and theories of psychology in a series of short science fiction stories. Selected for their ability to demonstrate psychological principles, their literary quality and engaging style, the stories are arranged to parallel the subject matter of general psychology courses. Extensive editorial notes help to focus on the concepts at work in each story. c. 400 pages, \$5.95 Paper

theories of motivation: from mechanism to cognition

Bernard Weiner, University of California, Los Angeles / Filling the need for an up-to-date text on motivation, this work provides an in depth analysis of the most important developments in the field and the latest experiments in casual attributions. c. 400 pages, \$12.00 Cloth

READINGS IN PERSONALITY

Edited by Harriet N. Mischel and Walter Mischel, *both of Stanford University*

This collection of articles presents major theories, issues, and research in personality. While the selections parallel the organization of Mischel: *INTRODUCTION TO PERSONALITY*, this book has been designed to serve as a complete independent volume. Extensive introductory material is provided to aid the reader in understanding the concepts presented by the individual articles. Selections in Part I offer samples of some of the major theoretical orientations to personality and their associated assessment techniques and applications. Part II covers personality development and basic processes.

1973/494 pages/\$6.95 paper

INTRODUCTION TO PERSONALITY

Walter Mischel, *Stanford University*

"Viewed strictly as a teachable undergraduate text, Mischel's new volume seems better organized, more clearly presented, and the most effective new work. While it carries a social learning, behaviorist orientation, it presents the major issues in the field in a succinct and remarkably pointed fashion so that the more humanistically oriented instructor can use the book to good advantage." Jerome L. Singer, *Yale University*, from the 1972 *ANNUAL REVIEW OF PSYCHOLOGY*.

Instructor's/Test Manual

1971/544 pages/\$11.00

MAINSTREAM PSYCHOLOGY: A Critique

Benjamin M. Braginsky, *Wesleyan University*, and Dorothea D. Braginsky, *Fairfield University*

MAINSTREAM PSYCHOLOGY reviews and analyzes the role of psychology as a profession and as a social force. Avoiding technical jargon, the book includes an analysis and critique of the methodology, theories and practices of psychology with particular focus on behaviorism and humanism. The book provides a social psychological model for understanding and evolution and development of the field, and integrates disparate criticisms of psychology and other social sciences into one comprehensive framework.

March 1974/182 pages/\$4.50 paper; \$7.95 hard cover (tent.)

BEHAVIORAL SELF-CONTROL

Carl Thoresen, *Stanford University, School of Education*, and Michael J. Mahoney, *Pennsylvania State University*

As man becomes more concerned about the advances of systematized behavior control, the importance of personal freedom and humanistic choice become more apparent. *BEHAVIORAL SELF-CONTROL* points out that the technology of behavior change can be meaningfully and productively self-applied toward personalized goals. Blending humanistic concerns and behavioral means, this interdisciplinary book offers a comprehensive data-oriented review and evaluation of existing theory and research on self-control.

What is the PSI?

For many years psychologists have recognized the need for an efficient, inexpensive means for identifying persons in need of thorough psychological appraisal.

Dr. Richard I. Lanyon of Harvard Medical School has developed a major new technique for assessing personality and psychopathology, the PSYCHOLOGICAL SCREENING INVENTORY. The PSI provides mental health professionals with a brief screening device appropriate for situations in which time and professional manpower are at a premium. It will be particularly useful to those charged with making professional decisions in community clinics, hospitals, high school and college counseling offices, referral agencies, medical facilities, courts and reformatories. Those doing basic research or evaluating treatment will also want to consider using the PSI.

There are five scales: *Alienation, Social Non-Conformity, Discomfort, Expression and Defensiveness*. PSI item content is neither offensive

nor threatening. Respondents answer True or False to 150 short items, which can be scored manually in three to four minutes.

Norms are provided and based on 1000 males and females drawn from four diverse geographical locations. Most helpful is the unusually wide variety of scores for reference groups (both clinical and deviant) included in the Manual.

For a complete PSYCHOLOGICAL SCREENING INVENTORY Examiner's Kit, including 25 Question and Answer Sheets, 25 Profiles, a set of 10 Templates and the PSI Manual, please complete the coupon below and mail it with your personal check or institutional purchase order number.

Spring Psychology Texts

CLINICAL PSYCHOLOGY: The Study of Personality and Behavior

SOL L. GARFIELD

an overview of the theory and practice of clinical psychology, its present state and future trends

Clinical Psychology presents a comprehensive and realistic overview and introduction to clinical psychology today. It covers all the main aspects of the field and provides a basic understanding of its history, diverse theoretical orientations, functions, and problems.

The book reflects the author's many years of experience as a leading scholar and practitioner in the field. He presents fairly and objectively all significant views and developments, suitably balanced between the seminal theoretical statements and research of the past and the most recent approaches

to problems of psychological dysfunction. The book is a major statement—coherent and thorough—of the present state and future trends in this important field of research and professional practice. Ideal as a basic text for a first course in clinical psychology, the book is valuable as a supplement for courses in psychology and in all other fields concerned with individual and community mental health.

456 pp. \$14.95 cloth \$8.95 paper*
March 1974

BEHAVIOR MODIFICATION PROCEDURE: A Sourcebook

EDWIN J. THOMAS, editor

a sophisticated "how-to-do-it" manual offering specific guidelines for practice with individuals and groups

This clear, lucid sourcebook is addressed to the specific procedures that practitioners must employ when engaging in behavioral assessment, modification, and case and program management. The 25 selections are drawn from a wide variety of areas of behavior modification procedure. *Behavior Modification Procedure* is an ideal basic text

for courses in behavior therapy and behavior modification, and psychotherapy. It is also a valuable supplement for introductory courses in psychological practice and interpersonal helping.

PSYCHOLOGY AND RACE

PETER WATSON, editor

The scope of *Psychology and Race*, the distinction of its contributors, and the hard-headed sense of reality it brings to the discussion of extremely complex issues make this book an invaluable resource and text for courses in Social Psychology and all courses dealing with race. It is divided into two main parts. The first looks at the interracial situation and analyzes it by breaking it down

into three interrelated sections. The second half looks at those areas of life where race is relevant and where psychology can help in an understanding of the situation, including such crucial issues as education, language, crime, mental illness, and nationalism.

February 1974

HUMAN BEHAVIOR IN THE SOCIAL ENVIRONMENT: A Social Systems Approach

RALPH E. ANDERSON and IRL E. CARTER

"This book is an attempt to map the territory of human behavior. It is intended to introduce students to ideas and theories that are fundamental to understanding such behavior. In our teaching and in our students' learning, we found that we came nearest to accomplishing this task by writing this book and using it as a global map of human behavior. It designates the major levels of knowledge of human behavior and enables the student to recognize with what human system he is concerning himself. It is designed as a textbook to organize human behavior content into an understandable whole."—from the authors' foreword

Using a social systems framework, this book is a pioneering attempt to provide a framework enabling students to integrate a vast array of concepts and knowledge about human behavior. It provides a large-scale map, intended to be supplemented in each particular sector of human behavior with more detailed maps of particular terrain that is of special interest and concern to future professionals in particular fields.

The first thing
we did with our
Human Development
series...

Was to find
a good-looking hero.

You see, our film strip series deals with **real people**—not cartoon characters. And through these real people you are offered a challenging look at the first 2½ years of life—the crucial years.

Effects of day care centers... sequence of language acquisition... effects of sensory stimulation on intellectual and emotional development. *Human Development* offers a provocative Old-vs-New cross-section of the theories and findings of the most noted authorities, including Piaget, White, Kagan and Bower.

Designed for students of education, psychology, home economics, and the social sciences, *Human Development* is far less expensive than movies—and far too important to overlook.

Psychology ADAPTED READINGS

Edited by JEROME KAGAN, *Harvard University*,
MARSHALL HAITH, *University of Denver*, and
CATHERINE CALDWELL

This unique collection offers an outstanding and highly readable selection of both classic works and recent studies in the major areas of psychology, adapted specifically for students in the introductory course. The editors' aim in adapting the articles was to make them completely accessible to the student; nonessential details and overly technical descriptions have been eliminated so that the basic concepts emerge clearly and forcefully. The book contains 35 readings organized around 14 major topics in introductory psychology; the readings illustrate both theoretical and empirical approaches and present contrasting, often opposing, points of view. Each topic is introduced by a brief headnote. Accompanied by a Test Booklet.

Paperbound. 404 pages. \$4.50

Psychology as Science and Art

JAMES DEESE, *The Johns Hopkins University*

Psychology as Science and Art offers a brief overview of the attitudes, methods, and approaches of modern psychology. The author discusses how psychological activities range from the strictly scientific to the strongly humanistic; he gives the student an understanding of what psychology can and cannot do and what the future of psychology is. A stimulating supplement that will promote lively class discussion, the book provides the instructor with a highly flexible teaching tool and offers the student an innovative treatment of the nature of psychology.

THE PSYCHOLOGY OF ADULT DEVELOPMENT AND AGING

*surveys what is known
and outlines the unexplored regions
of gerontological psychology*

A major product of the American Psychological Association's Task Force on Aging, this rich guide to gerontological research summarizes findings of outstanding leaders in the field and provides a fruitful source of testable hypotheses for investigators in almost every psychological specialty. Editors Carl Eisdorfer and M. Powell Lawton cochaired the APA task force, which was organized in response to a request for representation at the White House Conference on Aging (held November 1971).

The Psychology of Adult Development and Aging amply reaffirms the realization that chronological age is a poor indicator of an individual's cognitive and emotional characteristics. Emphasis is on identification of the contribution of other variables, demonstrating experimental, developmental, and clinical approaches. Topical coverage is unusually broad, ranging from animal and psychophysiological research to problems of education, housing, and transportation. (718 pages: \$11)

To obtain copies, write to the Order Department, American Psychological Association, 1200 17th St., N.W., Washington, D.C. 20036. Prepayment must accompany all orders amounting to less than \$15.

A New, Fresh Approach to Introductory Psychology

UNDERSTANDING HUMAN BEHAVIOR
by James V. McConnell of the University of Michigan

Comprehensive, dramatic introduction to principles of psychology emphasizing positive, constructive and rewarding approach to learning.

Human behavior analyzed from three points of view: intrapsychic, biological, and social/behavior.

Fictionalized case histories, experiments and illustrative stories provide intriguing preview of chapter content. Topics include: Sperry's split-brain work, Rosenhan's work on accurate sanity diagnosis.

Personal and social concerns fully developed in both textual and fictional material. Topics include: biofeedback, Transactional Analysis, human sexuality.

Research experiments presented from point of view of experimenter (why he/she planned it that way) and the subject (how he/she perceived the experiment).

Running glossary contains definitions of psychological terms, more difficult everyday words, related references, author's comments, and chapter summaries.

REVIEWER COMMENTS:

"I was immediately struck by the high readability of the chapters and the fictional vignettes beginning and ending each chapter. There is little doubt that J. V. McC. has apprehended his goal: an introductory psychology text written for all students."
Elliot Entin, Ohio University

"Overall, I would have to say that the work is very thorough, scholarly and well written, giving significant concepts in a generally interesting manner. It should appeal to students at a variety of intellectual levels."
Robert Hoeppner, Orange Coast College

"My general impression is that you've got a winner."

Charles G. Halcomb, Texas Tech University
720 Pages/February 1974/\$10.95 (tentative)

Also Available to Accompany the Text—
STUDENT MANUAL by Lawrence Al Siebert, Oregon State System,
and Timothy Walter, Rhode Island College

Provides a complete review of the textual material, a series of "prescriptions" on how to study and how to pass exams, detailed step-by-step reviews of chapter material, true-false test questions, individual action projects, and readings.
128 Pages/February 1974/\$2.50 (tentative)

INSTRUCTOR'S MANUAL by Lawrence Al Siebert and Timothy Walter.
Includes chapter summaries, content objectives (major learning points), list of films and sources, and suggested class demonstrations.
96 Pages/February 1974

TEST ITEM FILE BOOKLET by Lawrence Al Siebert and Timothy Walter.
Over 900 true/false and multiple choice questions laid out for easy assembly as a card file.
320 Pages/February 1974

How to Avoid an Energy Crisis

Soon it will be time for you to set up schedules, make plans, and choose textbooks for next fall. It's going to take a lot of energy! To help you avoid having an energy crisis, we suggest...

If you're teaching Personality Adjustment...

CONTEMPORARY PSYCHOLOGY AND EFFECTIVE BEHAVIOR

James C. Coleman and Constance L. Hammen
University of California, Los Angeles

This revision of *Psychology and Effective Behavior* explores the problems of human adjustment in light of the latest research findings. Scientific facts and research evidence are integrated with quotes from college students and others, helping your students relate these concepts to their own experiences. A Study Guide and Instructor's Manual are available.

March 1974, 576 pages, illustrated, cloth, approx. \$11.75

For your courses in Behavior Modification...

CONTROL OF HUMAN BEHAVIOR

Roger E. Ulrich, Western Michigan University
Thomas J. Stachnik, Michigan State University
John H. Mabry, Porterville State Hospital, Porterville, California

Volume I: Expanding the Behavioral Laboratory

1966, 349 pages, illustrated, paper \$5.95

Volume II: From Cure to Prevention

1970, 378 pages, illustrated, paper \$5.95

Volume III: Behavior Modification in Education

February 1974, approx. 448 pages, illustrated, paper, approx. \$6.95

We've expanded this excellent series to three volumes—the third one focusing on the application of behavior modification to varied educational settings. Ranging from infancy to adulthood, a thorough, comprehensive look at new programs in behavioral education is presented.

For the Comparative Psychology course ...
PERSPECTIVES ON ANIMAL BEHAVIOR

General Editor: Gordon Bermant, Battelle Seattle Research Center and University of Washington

A First Course: Ten Original Essays by John Alcock, Jarvis Bastian, Gordon Bermant, Robert C. Bolles, Thomas Harrington, Benjamin L. Hart, Peter H. Klopfer, Dale F. Lott, G. Mitchell, Robert M. Murphy, Benjamin D. Sachs, Robert P. Scobey

Three approaches to the study of animal behavior are woven throughout the chapters of this text: the zoological, the physiological, and the psychological. A sense of direct communication between author and reader and a sharing of each author's fascination with his topic as well as his knowledge about it has been emphasized.
1973, 416 pages, illustrated, cloth \$12.50

A new text in Learning and Cognition ...
THE STUDY OF BEHAVIOR
Learning, Motivation, Emotion, and Instinct

Editor: John A. Nevin, Columbia University

Consulting Editor: George S. Reynolds, University of California, San Diego

This balanced, distinctive text covers the topics of learning, motivation, emotion, and instinct, with special emphasis on learning problems. An innovative discussion of both recent and traditional issues is offered with a clarity of presentation that is unusual among texts of this type.

1973, 418 pages, illustrated, cloth \$10.95

A unique Social Psychology text ...
INTRODUCTION TO INTERPERSONAL RELATIONS

Clifford H. Swensen, Jr., Purdue University

This is the *first* textbook on interpersonal relations to provide an overview of the field as a whole. The text ranges from psychiatric to psychological to sociological theories.

1973, 474 pages, illustrated, cloth \$7.95

The Two Faces of Symbolic Activity

When Howard Pollio of the University of Tennessee decided to write *THE PSYCHOLOGY OF SYMBOLIC ACTIVITY*, he wanted to avoid the pitfalls of other books on the subject. He wanted to show both sides of the story. And so *this* book deals fairly with the two most significant general approaches to symbolic activity—associative and information processing.

In the words of the author: "... I have tried to write each chapter as an 'insider' might. So, for example, if I were writing an associative chapter, I have tried to write as an associative psychologist might, and if I were writing an information-processing chapter, I have tried to write as an information psychologist might."

Within the context of both of these approaches, Pollio treats the five topics of memory and forgetting, concept formation, problem solving, the development of thinking, and language and language use. And, in his exploration of the field, he deals directly as well as experimentally with each topic.

The book was written for junior/senior and graduate levels, and requires only introductory psychology as a prerequisite. (504 pp—1973—\$12.95).

SOME OTHER BOOKS OF INTEREST:

THE PSYCHOLOGY OF PERSONALITY by Wiggins, Renner, Clore, and Rose (705 pp, 95 illus—1971—\$11.25)

PERSONALITY AND PREDICTION: PRINCIPLES OF PERSONALITY ASSESSMENT by Wiggins (656 pp, 62 illus—1973—\$17.50)

THE ORIGINS OF ABNORMAL BEHAVIOR by Corah and Gale (448 pp, 5 illus, paperbound—1971—\$6.95)

FUNDAMENTALS OF BEHAVIORAL STATISTICS, SECOND EDITION by Runyon and Haber (351 pp—1971—\$8.95)

The Consolidated Roster for Psychology

A NEW LOCATOR-REFERENCE

Published as a Service to the Psychological Community
Compiled from the APA's 1972 Survey of Psychologists in the
United States and Canada

An alphabetized roster of over 45,000 professionals and graduate students, including all APA members and nonmember survey respondents. All levels of training and experience, a full range of employment settings, and all types of positions and specialty areas are represented.

Roster Contents include:

■ Alphabetized Listing

- Name
- Business or Home Address
- Business Telephone Number
- Primary Employment, including Graduate Study
- Two Psychological Specialties
- Highest Degree, Major Specialty Area, Institution and Year
- ABPP or ABPH Diploma Specialty
- State Licensure or Certification as a Psychologist
- Membership in the APA and CPA

■ Geographic Locator Index

United States, Canada and other Foreign Countries, organized by state or province, city, and primary employers. Private Practitioners and ABPP or ABPH diplomates are flagged.

■ Psychology Laws in the United States and Canada

A summarized presentation of the status of licensing and certification of psychologists.

■ Psychological Specialties

A classified reference list of the specialties and codes used in the Roster, including a list of abbreviations.

ORDER your Roster now using the coupon below and enclose your check, payable to the American Psychological Association.

INSIGHTS INTO HUMAN BEHAVIOR

Second Edition Stanley K. Fitch, El Camino College

Featuring the same clear, direct language as the first edition, this new edition has been revised to include new chapters on perception, deviant behavior and a discussion of alternate marriage styles. February 1974, Est. 425 pp.

PERSONALITY Applying Theory

Harold W. Bernard, Oregon State System of Higher Education

This new text examines personality theories in a humanistic context. It includes theories of historical significance when pertinent to the contemporary scene, as well as theories that are now in the active process of formulation. January 1974, Est. 425 pp.

CASE HISTORIES OF DEVIANT BEHAVIOR

Gloria Leon, Rutgers University

This is a new dynamic casebook for students in abnormal psychology or behavior modification courses. Professor Leon utilizes the social learning approach. Therapy techniques are also included wherever applicable. March 1974, paperbound, Est. 300 pp.

EDUCATION PSYCHOLOGY: Focus on the Learner, 1972, 604 pp. Lita Linzer Schwartz, The Pennsylvania State University, Ogontz Campus.

HUMAN BEHAVIOR IN A CHANGING SOCIETY, 1973, 382 pp. Edited by James F. Adams, Temple University.

DYNAMICS OF PERSONAL ADJUSTMENT, 1971, 421 pp. Harold W. Bernard, Oregon State System of Higher Education & Wesley C. Huskins, Wright State University.

The *American Psychologist* is the official publication of the American Psychological Association and, as such, contains archival documents as well as material submitted by authors. Articles should be timely and of broad general interest to psychologists of all scientific and professional persuasions. Manuscripts must adhere to the instructions on reference citations, preparation of tables and figures, manuscript format, etc., as described in the *Publication Manual of the American Psychological Association*. Manuscripts that do not conform to the style set forth in the *Manual* will be returned for revision. When in doubt about practices of the *Journal*, authors should examine a recent issue.

Articles under consideration or accepted by another periodical of general circulation are not acceptable. Also, articles accepted for publication by this *Journal* may not be reprinted elsewhere without APA permission. Comments should be submitted no later than two months from the date of the issue containing an article on which comment is made in order to ensure timeliness.

Submit manuscripts in triplicate, accompanied by a 100-120-word abstract, to Kenneth B. Little, American Psychological Association, 1200 Seventeenth Street, N.W., Washington, D.C. 20036.

Statements contained in the *American Psychologist* are the personal views of the author(s) and do not constitute APA policy unless so indicated. APA reserves the right to edit all copy and to refuse ads that are not in consonance with the principles of Title VII of the Civil Rights Act of 1964 (Equal Employment Opportunity).

Written permission must be obtained from the APA for copying or reprinting text of more than 500 words, tables, or figures. Address requests to the Permissions Office.

Copyright © 1974 by the American Psychological Association, Inc.

Subscriptions: Subscriptions are available on a calendar-year basis only (January through December). Nonmember rates for 1974: \$12 domestic, \$13 foreign, \$2 single issue. Write to Subscription Section, APA. **Reprints:** Authors may order reprints of their articles from the printer when they receive galley proofs. **Back Issues and Back Volumes:** For information regarding back issues or back volumes write to Order Department, APA. **Microform Editions:** For information regarding microform editions write to any of the following: Johnson Associates, Inc., 175 Fifth Avenue, New York, New York 10010; University Microfilms, Ann Arbor, Michigan 48106; or Princeton Microfilms, Princeton, New Jersey 08540. **Change of Address:** Send change of address notice and a recent mailing label to the attention of the Subscription Section, APA, 30 days prior to the actual change of address. Undelivered copies resulting from address changes will not be replaced; second-class mail is not forwarded unless subscribers notify the local post office in writing that they will guarantee second-class forwarding postage. Published monthly in one volume, 12 issues, by the American Psychological Association, Inc., 1200 Seventeenth Street, N.W., Washington, D.C. 20036. Printed in the U.S.A. Second-class postage paid at Washington, D.C., and additional mailing offices.

The American Psychological Association, founded in 1892 and incorporated in 1925, is the major psychological organization in the United States. The purpose of the APA is to advance psychology as a science, and as a means of promoting human welfare. It attempts to accomplish these objectives by holding annual meetings, publishing psychological journals, and working toward improved standards for psychological training and service.

In addition to the *American Psychologist*, the Association publishes 13 other journals: *Contemporary Psychology*, *Developmental Psychology*, *Journal of Abnormal Psychology*, *Journal of Applied Psychology*, *Journal of Comparative and Physiological Psychology*, *Journal of Consulting and Clinical Psychology*, *Journal of Counseling Psychology*, *Journal of Educational Psychology*, *Journal of Experimental Psychology*, *Journal of Personality and Social Psychology*, *Professional Psychology*, *Psychological Bulletin*, and *Psychological Review*. The APA also publishes *Psychological Abstracts*, the *APA Monitor*, a monthly *Employment Bulletin*, the *Biographical Directory*, the *Convention Program*, and the *Catalog of Selected Documents in Psychology*.

Freedom and Dignity

A "Functional" Analysis

J. DENNIS NOLAN *Ohio State University*¹

Behavior can be studied from a number of perspectives, and a "functional"² analysis of behavior could, in principle, be concerned with the relationship between behavior and a number of other variables. An approach that focuses primarily on the relationship between behavior and its effects on the environment has been called the *experimental analysis of behavior*, or sometimes, *operant analysis* (e.g., Skinner, 1969). An operant analysis of behavior centers not only on the topography or structure of a response, but also on the effects or consequences of that behavior. Behavior defined in terms of its consequences is said to be functionally defined (e.g., Ferster & Perrott, 1968). A technology developed by people working from an operant analysis perspective has been identified as behavior control technology, and interventions that draw upon this technology are often globally referred to as *behavior modification*.

In practice, functional analyses of behavior attempt to identify both the effects of the environment on behavior and the effects of behavior on the environment. When a functional analysis is directed toward "undesirable"³ behaviors, it may help to identify environmental variables that could be modified if attempts to modify the undesirable behaviors were considered justified. However, in itself, a functional analysis does not imply that modification should be attempted, nor does it im-

plicate any specific behavior as being the most appropriate alternative if it is decided that modification will be attempted. Once it has been decided that intervention will be attempted and, in addition, that the intervention will be based on behavior control technology, there is concern for behavioral alternatives to the undesirable behavior because specification of such alternatives is generally required in applications of that technology (e.g., Bandura, 1969). As a rule, specifications of behavioral alternatives are fairly precise, though in some cases they may not seem to be so (e.g., "reinforce anything else but that"). Even in the latter cases there is usually de facto specification, because some behaviors are more likely to occur than others and hence are more likely to be followed by "reinforcement." Since functional analysis is neutral with respect to the desirability of behavior, it necessarily cannot specify the alternatives. Therefore, such specification must be based on a value system, whether implicit or explicit (e.g., Bandura, 1969). Before a behavior modification program is begun, the designer of that program should be able to specify both the rationale for intervention and the outcome toward which the intervention is geared.

Skinner (1972) suggested that the use of behavior control technology can and should be extended to accomplish the design of a culture. Like any behavior modification proposal that involves the use of behavior control technology, this proposal requires the behavioral specification of the goal (in this case, a modified culture⁴) toward which the technological application is directed, as well as the rationale for intervening. Ideally, such a proposal would include a description of the ex-

¹ The author is deeply grateful to Jaques W. Kaswan, Harold B. Pepinsky, and Joseph H. Spitzner for extensive criticism of an earlier draft, and to an anonymous reviewer for several very helpful suggestions.

Requests for reprints should be sent to J. Dennis Nolan, Department of Psychology, Ohio State University, 1945 N. High Street, Columbus, Ohio 43210.

² In this article, the term *functional* is used in a "Skinnerian" sense. For a consideration of ambiguities in the use of this term by social scientists, see, for example, E. Nagel (1961, pp. 520-535).

³ The critical issues of "by whom" and "on what grounds" are not dealt with in this article. The interested reader is referred to T. Szasz (1960) and to D. Ausubel (1961) for two contrasting views.

⁴ The difficult question "What is a culture?" is not the focus of this article. Skinner's (1972) conception of culture as a social environment or a set of contingencies of reinforcement, however arguable in its own right, will remain unchallenged in the present discussion.

pected effects of the proposed application of technology on as many aspects of the environment as possible. At the very least it should articulate the value system on which the specification of goals is based. Again, though, a functional analysis per se does not provide either specification.

Skinner (e.g., 1961a) asserted that survival is the only value that can reasonably be used to justify the design of a culture. This argument rests on two critical inferences drawn from a "directional" conception of cultural "evolution" (Skinner, 1972, p. 129).⁵ Additionally, he argued that science (specifically, operant analysis) offers the best perspective from which to implement his valued outcome. His rationale for introducing behavior control technology is that it is a scientifically based technology and that it is ethically neutral (p. 150). He implied that since science's models of human nature are "value free," a technology that is based on a scientific model is also value free. Hence, a concern for value judgments is largely beside the point (pp. 101-102). Further consideration of the philosophical and inferential issues involved seems warranted.

Skinner (1972) identified the strong commitment to the values of "freedom" and "dignity" that exists in our culture and presented intriguing arguments about some likely effects of maintaining these values. Nevertheless, the strength of these values in our culture is simply a fact in a functional analysis, and such an analysis would necessarily uncover both their existence and prevalence. For Skinner, however, the commitment to freedom and dignity values is *undesirable* for two related reasons. First, the presence of these two values may be precluding, at least indirectly, the acceleration of the "evolution" of our culture (e.g., 1972, p. 163). Second, if such evolution is not altered (it is unclear whether simple acceleration would suffice) our culture will develop, or perhaps is already developing, a fatal flaw, which could allow some other culture to make a greater contribution to the future (p. 183).

It may indeed be reasonable to assume, with Skinner, that commitment to the values of freedom and dignity is affecting the evolution of our culture. That assumption is not questioned in this article. However, the conception of "rate" of cultural evolution, implied in Skinner's analysis, can be seriously challenged. In the absence of an in-

dependent value system, an argument for accelerating the rate of cultural evolution implies the assumption that such evolution is necessarily moving in a desirable direction. However, unlike biological evolution, cultural evolution is at least partially revocable and is not subject to natural selection as such (e.g., Mead, 1958; Simpson, 1958). Hence, its "directionality" is highly questionable (e.g., Popper, 1964, pp. 105-119). In the absence of direction, rate is not a very meaningful parameter of cultural evolution (e.g., Popper, 1964, p. 114). Therefore, the rate of cultural evolution cannot serve as the basis for rejecting the values of freedom and dignity regardless of whether such evolution is affected by those values. Even if cultural evolution is affected by those values, it is not evident that any such influence would be undesirable.

Skinner's second objection to the prevalence of the values of freedom and dignity is related to the first. It rests on the assumption that "our" particular culture should be preserved at the expense of any other culture. Since for Skinner (1972, p. 182) a culture is defined as a set of contingencies of reinforcement, his argument is essentially that one particular set of contingencies of reinforcement should be maintained at the expense of any other set. A clear statement of the rationale underlying his preference for that set of contingencies is needed. Skinner (e.g., 1961a, p. 34) equated survival of his culture with the survival of mankind, an enormous inferential leap for which he has provided no substantiation ("rate" of cultural "evolution" clearly does not serve that purpose). Even if it were granted that the survival of mankind is the only defensible value, it still would not follow that Skinner's culture, or any other particular culture, must survive in order for mankind to survive. In the absence of an articulated set of values relating to the ways in which people "ought" to behave, no reason for perpetuating a particular set of contingencies of reinforcement (culture) is self-evident, and, as a result, no reason for rejecting the notions of freedom and dignity is apparent.

A Rationale for Adopting a Technology

If it were possible to provide a satisfactory specification of end states, an argument for systematic introduction of behavior control technology could be based on the assumption that the application of that technology would be likely to accomplish a desired goal. However, it would remain essential

⁵ Again, the difficulty in satisfactorily defining such terms as these is not at issue in this article.

to avoid concluding that what is technically feasible is desirable. Technologies that may accomplish desirable ends, while producing other states that are, or can reasonably be expected to become, intolerable, should also be avoided. The parallel with the development and proliferation of mechanical-industrial technologies is direct. The just now emerging, but long predicted, threatening side effects of such proliferation (e.g., pollution, the destructiveness of weapons) should induce grave concern. Unfortunately, Skinner does not seem to be concerned. For example, he suggested that the question of values is no more salient in the design of a culture than in the design of a bomb (Skinner, 1961b, p. 545). But different designs (whether of cultures or bombs) produce different costs and different side effects, some trivial, some nontrivial. The question of values arises in both cases, rather than in neither case, as Skinner implied.

Perhaps the most undesirable "side effect" of Skinner's proposal is that, in the absence of an independent basis for specifying cultural goals, the technology itself is likely to dictate those goals. (A quote from *Walden Two* in which Frazier says, "Eventually we shall have no use for Planners at all," suggests that Skinner considers this to be a *desirable* outcome [Skinner, 1962, p. 273].) A major danger in allowing the technology to define goals is that the adoption of a technology without independent consideration of goals probably limits the ways in which problems can be considered or construed and may also limit the number of alternatives that will be considered as possible solutions. The adoption of a technology, any technology, must await the emergence of some consensus about cultural goals, or some other basis on which to specify such goals.⁶ Reliance on a technology to dictate the efficient, or "efficiently reachable" (in terms of that particular technology), goal would not insure a wide variety of possible end states and could easily preclude such a variety.

Skinner proposed to examine how a society must be designed if it is to achieve its ends through positive reinforcement. Note that this proposal is to base the design of the society on the efficient use of an available technology (in this case, positive reinforcement), rather than on the specification of a particular outcome and the subsequent

design of ways of achieving that outcome. As desirable as it is to avoid the negative side effects that can accompany the use of punishment, the a priori selection of a "technology" that precludes the use of punishment does not insure the specification of good end states. It would be preferable to include concerns about side effects in the specification of end states, prior to the selection of a technology and then to find or devise a technology that can accomplish the specified end state. Such a technology may or may not include punishment (e.g., Solomon, 1964), but in either case, its adoption would be based on the expectation that the technology could accomplish what was wanted, not on an arbitrary a priori basis.

Consider Skinner's position with respect to the elimination of unwanted behavior. Skinner (e.g., 1972) suggested that, from a purely technological standpoint, a good long-run way to eliminate unwanted behavior is to completely eliminate the positive reinforcement that maintains the unwanted behavior such that it eventually becomes extinguished. One way of facilitating this process is to provide positive reinforcement for behaviors that are incompatible with the unwanted behavior. However, this procedure requires the specification (either precisely or imprecisely) of a repertoire that is considered rewardable, a feat that societies generally seem much less capable of accomplishing than the specification of unacceptable repertoires. Societal judgments seem reasonably consistent with respect to what is not tolerable, but not with respect to what is inherently valuable. Hence, procedures designed to suppress "unwanted" behaviors are rationally more defensible than those designed to increase incompatible behaviors, since the specification of behavioral alternatives cannot be made on any grounds but expedience. If society can only specify unacceptable repertoires, pervasive reliance on a technology that is designed to produce desired repertoires would not make sense.

End states involving standardized codes for dress, hair style, etc., which exist in many of our institutions (e.g., schools), often seem to precede, rather than derive from, the "value" with which they are identified when challenged (e.g., "propriety," "neatness," "custom"). Sometimes it seems as if these values are identified only when the end state has been challenged. Skinner (e.g., 1972, p. 105) could suggest that such values are simply classifications of things in terms of their reinforcing effects; they are simply "facts" determined by evolution and do not need to be related to some independent value system. However, there is an

⁶ Even the emergence of such consensus would not necessarily validate pervasive cultural design (e.g., Popper, 1964, pp. 152-159), but that issue is beyond the scope of this article.

other plausible interpretation. Behavioral standardization may be likely to be specified as a goal simply because it is technologically feasible to attain that goal. For example, it would seem plausible for a school to try to maximize individual differences rather than to standardize behavior and to search for a technology that could be of help in achieving that goal if the current technology either is not capable of doing so, or cannot efficiently do so. If a behavior control technology were adopted on a priori grounds, and if no independent basis existed for the specification of end states, the specification of end states like maximizing individual differences would be less likely, since, as Skinner himself implied (e.g., 1972, p. 162), these goals are less efficiently reached by such technologies.

Regardless of whether science is ethically neutral, a particular technology at any given stage of development will not be equally efficient at accomplishing all goals. In the absence of an independent basis for specifying goals, the technology is likely to dictate those goals which it can most efficiently accomplish. Such goals are not necessarily ethically neutral. It may be noted that Skinner (e.g., 1972, p. 162) also criticized institutions like schools for breeding uniformity, and he argued for planned diversity. Yet he did not articulate a rationale for specifying diversity as a goal. In the absence of such a rationale, it is not likely that goals like diversity will be dictated by behavior control technology itself.

Skinner suggested that our current technology, however unsystematic it or its applications may be, also controls behavior—whether or not such control is planned. It may be true that the technologies currently employed do produce outcomes that are predictable, at least in principle. Even if this assertion is valid, it does not follow that we should therefore *value* an increased ability to make such predictions, nor does it follow that we should value the specification of end states or the ability to control them. Such values do not derive from functional analyses. In effect, the specification of end states is only required if behavior control technology is adopted. It is a technological requirement rather than a scientific requirement, and in the absence of the technology no reason for valuing the specification of end states would be self-evident. As Freedman (1972) pointed out, it is possible to use scientific principles similar to those employed by Skinner to devise a model of a good society quite different from the one that Skinner proposed. In order to

do so, one need only specify end states on the basis of a value system different from Skinner's unarticulated value system. If such specifications were made, behavior control technology might indeed be useful. However, there is no warrant for assuming that reliance on technology for the specification of end states would be more likely to result in a "good" culture than our current haphazard (from Skinner's perspective) procedure.

In summary, there are at least three good reasons at present to avoid strong reliance on behavior control technology for "improving" human societies. First, Skinner's assumption that a good end state will result from an accelerated rate of cultural evolution can be rejected on logical grounds, thereby rendering the adoption of the technology pointless. Second, although behavior control technology might accomplish some desirable goals, if it were adopted in the absence of an independent value system it would also produce undesired side effects in the process, as well as unintended and unexpected effects (e.g., Popper, 1964, pp. 64-70). Finally, the precise specification of end states may not be valued (and may even be devalued). If so, the adoption of behavior control technology would lead to an undesirable goal, because that technology will itself dictate end states.

Motivation and the Cognitive Revolution

WILLIAM N. DEMBER *University of Cincinnati*¹

A great deal has happened to psychology in general and motivation in particular in the decade since I prepared the article "The New Look in Motivation" (Dember, 1965). The most striking development—significant enough to be termed *revolutionary*—is one that I will attend to exclusively in this article: Psychology has gone cognitive, and so has motivation. Indeed, part of the impetus for the movement of general theory and research toward cognition was provided by dissatisfaction among motivational theorists with the prevailing stimulus-response (S-R) behavioristic model that had characterized American psychology for several decades.

The purpose of the present article is twofold: (a) to elaborate on the assertion above that motivation has actively participated in the cognitive revolution and (b) to point out some behavioral phenomena, more from the "real world" than from the laboratory, that are not yet satisfactorily handled even within modern, cognitively oriented motivational models. These are phenomena, nevertheless, that demand a cognitive interpretation. What I would like to accomplish here, above all, is to prod future theorists into a "newer look" in motivation, one which can cope with these compelling, but elusive, phenomena.

This article is organized according to its dual aims. First, I will discuss the cognitive revolution both generally and also specifically as it pertains to motivation. Then, I will indicate some kinds of behaviors which I believe must be accommodated by any motivational model that strives to be comprehensive. The theme of this article, then, might be, "You've come a long way, baby. But the trip isn't over yet."

¹This article is based on talks given at Xavier University and Edgecliff College in Cincinnati, at Western College in Oxford, Ohio, and at the University of South Florida in Tampa.

Cognition in Psychology

One of the assets of science is its cumulative nature. New data supplant old; new ideas replace outworn ones. The growth of scientific theories may be continuous, through a process of modification and accommodation, or it may at times be discontinuous, through the introduction of radically new concepts or, in Kuhn's (1962) term, *paradigms*. In either case, there is in the history of science a sense of linear progression.

The history of psychology certainly contains its share of growth. New data typically are better than old, largely a result of improved techniques and methodology. And new theories generally are at least more sophisticated than their predecessors, by virtue both of the existence of better data and of access by theorists to more highly developed symbolic (often mathematical) structures on which to hang their ideas. Nevertheless, there is also in psychology a disappointing lack of conceptual progress: Instead of developments which are incremental, we seem all too often to witness a kind of circularity. Our newest ideas are terribly reminiscent of our oldest ones; they carry us around the board and back to "Go." Hopefully, these paths will ultimately turn out to be expanding spirals rather than circles, and conceptual progress will be made.

It is too early to know whether what I am calling the cognitive revolution is really that or whether psychological theory has just come full circle. Be that as it may, what is quite clear is that cognitive concepts have begun to pervade many areas of psychological theory.

Psychology was said to have "lost its mind" with the advent of Watsonian behaviorism in the second decade of this century. In his attempt to rid scientific psychology of data achieved through nonobjective means (a goal with which it is hard for scientifically oriented psychologists to quarrel), Watson also cleansed the field of mentalistic concepts. In the textbooks, until very recently, psychology was no longer defined as "the science of experience," but rather as "the science of behavior."

Problems that seemed to rely on introspection-generated data for solution were taboo; feelings, images, percepts, ideas—as concepts within a theory—were proscribed. Theory was to be constructed, if at all, out of physical “stimuli” and muscular “responses.”

That confusion of methodological purity with conceptual barrenness had at least two implications. First, it deprived psychology of most of its interesting problems. Second, S-R theorizing proved inadequate to the task.

Memory and Language

S-R theory, with its close conceptual ties to Pavlovian conditioning and instrumental learning à la Thorndike and Skinner, is most readily applied to simple learning situations; for example, salivary conditioning in dogs, T-image learning by rats, key pecking in pigeons, eyelid conditioning in human subjects. Even in those settings it has its inadequacies, but they only become serious when the S-R model is stretched to fit more complex situations. In particular, the weakness of S-R theory has been most clearly exposed in two areas of research, human memory and language.

In the case of memory, to summarize a vast and complex literature in a brief paragraph, the evidence is quite compelling that in storing and retrieving large numbers of items, people employ active strategies; they do not function as passive receptacles, or *tabula rasa* on which associative bonds are imprinted and then remain available for later activation when the proper stimulus comes along. One such strategy is called *chunking*. As the word suggests, several separate items are formed into a single unit and by that transformation become less of a burden on the memory system, as, for example, when the following list of eight digits, 1, 5, 2, 0, 1, 9, 0, 6, is stored and retrieved as the four units “fifteen, twenty, nineteen, six.” Another strategy that people follow in learning and remembering arbitrary associations is to employ images as mediators among the items to be associated. It turns out that weird, or bizarre, images are especially good for this purpose (e.g., see Segal, 1971).

The recent study of language behavior has had profound impact on psychological theory, much of it attributable to the contributions of the linguist Naom Chomsky and his colleagues (e.g., see Chomsky, 1959). One target of this group is an S-R analysis of language proposed by Skinner (1957).

The arguments are complex and beyond the scope of this article. The outcome is quite clear, however. Language, the hallmark (if not the unique possession) of human beings, cannot be treated simply as a set of associations acquired according to the principles of operant conditioning and elicited by arbitrary stimuli. It remains to be seen whether Chomsky's own “generative grammar,” with its assumption of innate “deep” linguistic structures, will prove an adequate substitute for a simple behavioristic model. In any event, neither “psycholinguistics” nor general psychology will go untouched by the Chomsky-stimulated developments. Again, perhaps grossly to oversimplify, the point here is that it has become respectable, if not essential, to restore to psychological theory those complex, “cognitive” processes that behavioristic models tried valiantly to get along without.

In the case of language it is quite evident that theoretical progress has been made. We are not simply back where we were when Watson got us off the track. First, the careful, self-conscious efforts of Skinner and others to apply S-R theory to language behavior has made it possible to identify the specific deficiencies of such an approach. Second, the recent theoretical developments are far more articulate and precisely formulated than their largely intuitive pre-Watsonian forebears. Moreover, they are based on, and have generated, a solid body of clearly conceived and executed empirical research (e.g., see Dixon & Horton, 1968).

Perception

For the most part, the field of perception has been relatively impervious to the impact of behaviorism. Researchers and theorists in perception reacted to the strictures of behaviorism primarily by attending more carefully to their methods, but the problems they investigated and their conceptual models proceeded along relatively smooth and continuous paths. It may not be irrelevant that the major figures in perceptual theory (the Gestalt psychologists, Wertheimer, Koffka, and Köhler) during the ascendancy of behaviorism totally rejected its tenets as they applied specifically to perception and cognition as well as generally to the way the brain worked (the organ which presumably controls all psychological processes).

In the sense that perceptual theory has gone its own way over the past 50 years, it has also not been much affected by the recent cognitive revolution. Indeed, one major development in perceptual

theory, spanning the 1940s and 1950s, can be said to have anticipated the trends becoming apparent in other areas. I am referring to the "new look in perception," which, as pointed out in my "New Look in Motivation" article, argued for cognitive and affective influences on such basic perceptual processes as the recognition of and attributive judgments (e.g., How large is this coin?) about stimulus objects. This approach to perception represented a reaction, not against behaviorism, but rather against the Gestalt emphasis on purely stimulus determinants of perception. Of course, the Gestaltists' conception of what constituted a "stimulus" was itself quite dynamic; it insisted on the relational nature of perception, whereby the perceived value of a particular stimulus element is determined jointly by its own physical properties and the properties of the total stimulus field in which it is embedded. For example, a given spot of illumination can be made to appear either black or white depending on the intensity of the surrounding illumination.

Proponents of the "new look in perception" argued, in effect, that the definition of the embedding context be extended to include properties of the perceiver, such as his motives, habits, conflicts, and expectancies. How successfully that point has been demonstrated empirically remains, unfortunately, an open issue. Nevertheless, by asserting the influence on perception of cognitive, affective, and motivational processes, the new lookers did, perhaps inadvertently, open up the possibility of influences in the other direction as well. That is, as I have argued earlier, the "new look in perception" in part paved the way for a "new look in motivation."

Motivation

There is obviously no need to retell the whole new look in motivation story. It can be summarized in a sentence: Human beings and lower animals are attracted by, and their behavior is reinforced by, the informational properties (e.g., novelty, complexity) of stimuli in much the same way that they are influenced by stimulus intensity or whatever it is that gives potency to the conventional, "homeostatic" incentives and rewards. For the present purpose, however, that sentence can usefully be elaborated. But first, I simply want to assert that an impressive body of research, obtained from a wide variety of subjects, animal and human, young and mature, conducted since my new look in moti-

vation article was written, overwhelmingly supports the basic point in the summary statement above. That is not to say that the literature, like others, does not contain its share of confusions, contradictions, and controversies. Nevertheless, the motivational significance of information is by now firmly based in sound, empirical evidence.

It is the relation of this development in motivational theory to the "cognitive revolution" that needs further, but brief, explication. In effect, over the past three decades a profound change has taken place in the manner of conceptualizing those events considered motivational in nature (drives, incentives, rewards, etc.). In Clark Hull's (1943) highly influential *Principles of Behavior*, those events were tied directly to conditions of physiological imbalance, or "need." Behavior was instigated by departures from optimal physiological states and reinforced, or "rewarded," by restoration of physiological balance. Hunger (operationalized as "food deprivation") and reinforcement of hunger-reducing behaviors (through ingestion of food) provided the prototype of the processes linking motivation and learning. Hull's choice of a physiological definition of motivational variables was dictated by his general biological, Darwinian orientation to psychology and his concern for objective, operational anchors for "tying down" psychological concepts.

But Hull's strictly biological approach proved too confining; it was relatively easy to find instances that contradicted the expected one-to-one correspondence between biological needs and behavioral indicants of motivation. Thus, needs could be cited which seemed to have no direct behavioral consequences, and behaviors indicative of strong, underlying motives could be identified for which there seemed to be no corresponding need. The realm of behaviors referred to as "exploratory" or "curiosity motivated" provided a rich source of compelling examples.

Hull's student Neal Miller dealt with this problem by redefining motives (*drives*, in his terms) and rewards. A drive, in Miller's scheme (e.g., see Dollard & Miller, 1950), was "any strong stimulus." Now, strong stimuli *can* arise from biological needs (e.g., the hunger pangs that often accompany prolonged food deprivation), but they are not tied exclusively to needs. Rewards, in Miller's scheme, are provided by the reduction in the intensity of strong stimulation: reward = drive reduction. Such rewards (e.g., food for a food-deprived animal) may be need reducing but, again, not necessarily.

In effect, Miller gave a *sensory* definition to Hull's basic motivational concepts, and thereby started motivational theory down the cognitive path. The crucial motivational aspect of stimulation, for Miller, was its intensity—intensity as a *physical* property of stimuli. Tying drives to physically measurable properties of stimuli in this way allowed Miller the objectivity required of his general S-R behavioristic approach. But it had the same confining effect as Hull's tying motives to biological needs. It became all too easy to find examples (in "thought experiments") of motivational events, the impact of which was related not to their physical properties per se but to their significance or meaning to their perceiver. These examples include instances in which increasing stimulus intensity is rewarding and where decreasing intensity of stimulation might increase, rather than reduce, drive level. Consider, for example, a person lost in a cave, searching for an exit. It is totally dark. Suddenly he sees in the distance a dim light; he moves toward it, and as the light gets brighter he realizes that he is seeing sunlight through an opening in the cave. Surely the increase in light intensity is a rewarding event. Now, reverse the sequence, the imagine being alone at night in a strange house; suddenly all the lights go out. Is that a rewarding event?

Clearly, stimulus intensity by itself cannot carry the whole motivational burden. Changes in intensity of stimulation can be either drive reducing or drive inducing, depending on the total context in which they occur. In other words, without knowing certain things about the perceiver of the stimulation, it is unlikely that taking physical measurements of stimulus intensity will provide a sufficient basis for inferences about motivational states.

One can remain committed to intensity as the key motivational variable and still get out of the trap Miller set for himself by giving up physicalism and turning inside the organism. What counts then is not necessarily stimulus intensity (although it may be highly relevant in many instances), but the organism's internal responses to stimulation, as evidenced perhaps by level of activation of the autonomic or the central nervous system. In short, the key variable becomes "arousal" intensity, instead of stimulus intensity. Drives, then, might be defined as states of high arousal, and rewards as reductions in arousal level. From this point of view, stimulus seeking, exploration, and so on are seen as behaviors that generate increases in stimulation in the service of reducing the high arousal

level which accompanies sensory deprivation or boredom (e.g., Myers & Miller, 1954). Berlyne (1960) built an entire theory of curiosity and aesthetics around that notion.

Now, what the arousal model does in essence is to collapse all possible psychological dimensions onto the single dimension of physiological arousal. That is, it is arousal level that determines which behaviors will occur; what the determinants of arousal itself might be are of secondary interest. So, if one could tap the arousal lines and read arousal level on a voltmeter, then one would have access to all the information necessary to make accurate behavioral predictions.

Such an approach might prove valid, but even so it seems unsatisfying. Too many issues are skirted. Psychologists do care about what people perceive and think and why, for example, certain events are arousing for some people at some times. It may be that ultimately these various psychological processes do all pass through a single blender ("arousal") and come out undifferentiated glop at the other end, but what they were like before becoming homogenized may still be worth asking.

An alternative approach to one that employs arousal as the mediating variable is to stick with events as perceived or otherwise processed ("understood," "categorized," "associated to," "imaged," or what have you) and to search for the properties of these events that relate to the behavioral choices that people and animals make. That class of models, referred to earlier under the general rubric of "the new look in motivation," which emphasizes the information value of events, is one such alternative approach to an arousal model. For present purposes the point to be made is that "new look" models clearly invoke processes that would generally be classified as "cognitive." It is in that respect that these models have moved motivational theory, along with other areas of psychology, in the cognitive direction.

The same impetus has come from other sources as well. Cognitive dissonance theory, for example, is concerned with the generation of a driveline state through cognitive manipulations; indeed, some dissonance research has demonstrated that conventional drives, like thirst and hunger, can be influenced by cognitive-dissonance-arousing manipulations, for example, as when the level of hunger is reduced following a person's voluntary commitment to go several additional hours without eating following an agreed-on period of food deprivation (Brehm, 1969; see also Zimbardo, 1969, for a series

of related articles). Similarly, an impressive array of experiments has shown that the emotional impact of autonomic arousal is highly dependent on the context in which the arousal occurs—context provided by manipulations that clearly are mediated by cognitive processes (e.g., Schachter & Singer, 1962).

The conception of motivation in American psychology has thus considerably broadened over the past three or four decades. One effect of this development has been to allow increasingly complex and increasingly interesting behavioral phenomena to be incorporated into a scientific framework. The burden of the following section is to point to behaviors which are certainly interesting but which cannot yet be handled in any obvious way within current motivational theories, even the most cognitive of them. These behaviors suggest that “ideas” can be very potent motivators, not just mimicking, moderating, or influencing the “biological drives” but even at times overriding them.

The Motivational Potency of Ideation

Before proceeding, we need to agree on the nature and intent of what follows: (a) The material is presented not as evidence supporting a particular hypothesis, but rather as a collection of anecdotes and observations which, en masse, are suggestive of a hypothesis; (b) no anecdote or behavioral observation is subject to only one convincing interpretation; many of the items that are cited could be employed, as some have been, to make a different case from the one I am advocating; (c) so, my purpose here is to parade before you examples of behavior which suggest to me a serious gap in current motivational models—again not to make a case for a hypothesis but to indicate why it might be worthwhile to entertain, develop, and ultimately try to test a hypothesis of “the motivational potency of ideation.” Let the parade begin.

LABORATORY STUDIES OF COMPLIANCE

Virtually every experiment in psychology is, willy-nilly, a study in compliance. Potential subjects write their names on sign-up sheets, show up with remarkable reliability at the right time and place, and then proceed to follow as best they can the instructions given to them. We typically pay little attention to this chain of compliant acts; if we had to account for it, we would most likely turn to explanations that involved such concepts as role

playing (“being a good subject”) or specific motives, such as “conformity,” “need to please authority figures,” “altruism,” perhaps even “curiosity,” and so on.

Of course, and more to the point, there are countless experiments specifically designed to investigate compliant behavior. In these, the centrality of compliance is highlighted because it occurs in the face of serious counterpressures. For example, in Asch-type conformity experiments (e.g., Asch, 1956), subjects go along with group consensus even if it requires making perceptual judgments which are far from veridical. More dramatic are the obedience experiments of Stanley Milgram (1963), in which subjects followed the experimenter’s orders, often with considerable personal distress, to apply what they believed to be increasingly intense electric shocks to fellow subjects serving in a purported learning study. Apparently, ordinary people can be induced, by relatively uncoercive means, to engage in what would be viewed outside the laboratory as highly aggressive, perhaps sadistic, acts. But these were not sadists; they were simply normal people following orders. They could have refused to comply, but very few did.

For many such subjects, what they were doing was personally repugnant, but they did it anyway. Why? The simplest answer would seem to be “because they were told to” by a credible, persistent “scientist,” to be sure. That is, people do not blindly follow all orders; the setting needs to be just right. But in the right setting, being told to do something is tantamount to being motivated to do it. The experimenter’s instructions, once “planted,” take on the function of powerful, internally generated drives. (I wonder how hungry a person would have to be before he would deliver what he believed to be very painful shocks to a fellow subject in order to get access to food.)

HYPNOTIC SUGGESTION

The power of hypnotic suggestion is well known. Hypnotized people can be induced to engage in a wide variety of unusual behaviors, some of them quite antisocial or self-destructive. The literature on hypnosis is vast and confusing. Indeed, there is serious doubt as to whether it is necessary to invoke a special state of consciousness to account for hypnotic behavior (e.g., see Barber & Calverley, 1963). Attempts to uncover the essence of hypnotic behavior have revealed that nonhypnotized subjects, either faking or simulating hypnosis, do much, if

not all, of what "genuinely" hypnotized subjects do. That is, people can accurately "role play" the hypnotized subject. Whether that means there is nothing more to hypnosis than serious role playing is an open question. I allude to these observations here as a reminder that people, either under hypnotic suggestion or just simulating hypnosis, can be programmed, via the hypnotist's verbal instructions, to engage in behaviors that have all the earmarks of an intense underlying motivational state. That is, if one were to observe their behavior without knowing anything of its origins, one would be hard pressed not to give it a motivational interpretation.

REAL-WORLD EXAMPLES

My own interest in the issue under discussion was aroused not by laboratory research of the sort alluded to above, but rather by examples of behaviors reported in the news media that seemed to demand a motivational interpretation, but for which the standard, "dynamic" interpretations were vaguely unsatisfying. They all involve destructive and/or self-destructive acts—not too surprisingly given the temper of the times. Consider just four of a myriad of examples:

- A young boy died a slow, painful death after ingesting some solvent he had stolen from the school shop. Apparently some of his friends had dared him to do it.
- A 24-year-old truck driver won a \$500 bet from two of his friends by jumping off the George Washington Bridge—a 212-foot plunge into the Hudson River. He did not live to collect the bet (reported in the *New York Times*, May 9, 1971).
- Diana Oughton, daughter of a wealthy mid-western family, described as sensitive and warm-hearted, was killed with two Weathermen companions when bombs that they were constructing in a Greenwich Village apartment exploded (extracted and paraphrased from a book review by Fred J. Cook, in the *Saturday Review*, May 1, 1971, of a biography, *Diana*, written by Thomas Powers and published by Houghton Mifflin).
- An assistant pastor and a layman of the Holiness Church of God in Jesus Name, of Carson Spring, Tennessee, died in agony after drinking a mixture of strychnine and water—testing their faith in the Bible, where in Mark 16:16–18 it is asserted of those that believe that "if they drink any deadly thing, it shall not hurt them" (described more fully in *Newsweek*, April 23, 1973).

The last two examples, Diana and the strychnine drinkers, are illustrative of what I believe is the most potent form of ideation, that is, political or religious *ideology*. I do not know whether we are dealing with a continuum or with qualitatively distinct categories, but clearly when ideology prevails, ordinary motives look pale and insignificant. Think of Mahatma Ghandi going for weeks without eating; think of countless religious martyrs and political prisoners undergoing torture and death in the service of their faith, their party, or their country. Think of what must be otherwise gentle, loving, moral men and women killing and maiming innocent men, women, and children so that their side can win out in the current conflict in Ulster.²

The point, if its not already obvious, is that some of the dramatic behaviors demanded by a particular ideology must occur in the face of considerable counterpressure. By analogy with the old obstruction box method for assessing the relative strengths of rats' drives (how much electric shock will a rat endure in order to get access to a given type of incentive?), the intensity of this presumed counterpressure is suggestive of the extreme potency of the ideology-based motivation.

Needed: A Good Model

How can we transform these observations and inferences into a scientifically respectable theoretical model so that, among other things, they become susceptible to empirical investigation? I wish I knew. I must confess that I do not even know what form such a model might take, more, I hope, than just a collection of carefully worded sentences.

I am ready to suggest that one lead to model building in this area is provided in D. O. Hebb's (1949) *The Organization of Behavior*. Hebb made the cogent point that the directionality of a train of thought is just as much the expression of a motivational process as are the choices a rat makes running in a maze. In the case of ideology and its less intense counterparts, we seem to have trains of thought, or rather whole "transportation systems," dominating other sources of behavioral control. Furthermore, considering ideology in particular, we have not only a dominating system of ideation, but one that is capable of overriding all other motiva-

² My colleague, Harold Fishbein, has called to my attention some very pertinent comments about aggression and ideology by Arthur Koestler. (See especially Koestler, 1967, pp. 225–239.)

tional influences. Thus, whereas Stanley Milgram's subjects suffered great emotional stress in delivering intense electric shocks to their victims, I suspect that blandness, or else pleasant excitement, more nearly characterizes the emotional state of the ideological assassin. That is, the conflict is minimal as ideology overrides conscience or even impulses toward self-preservation.

Override, then, is one important property of ideology. Another, I think, is analogous to the physiological dependence that is associated with drug addiction. Call it *ideational addiction*. That is, the ideological convert is captured by his ideology; it is not just dominating, but also pervasive, persistent, and insatiable. Unlike ordinary motives, which are cyclic, ideology is constant, and instead of being reduced through consummatory activity it is either unaffected, or perhaps even enhanced.

This notion of ideological addiction might be handled in the language of a model that would also accommodate the property of override, by a concept such as *locking in*. That is, once an ideological addiction has occurred, it becomes, in effect, a permanent structure in the system. As such, I would guess, ideological addictions are much easier to acquire than they are to get rid of. Indeed, it may be that a new ideology must be available to substitute for an old one, if the old one is to be dropped—very much, it seems, as is the case with Kuhn's scientific paradigms referred to at the beginning of this article.³

Cognition and Evolution

It may be of some interest to consider the foregoing in the context of evolution. In that context, the morphological structures through which an organism's behavioral repertoire is put into effect (the limbs, glands, and other "effector organs") serve as means to assure individual and species survival. And the same holds for the structure, the nervous system, which integrates and controls the activity of the several effector organs. In that sense, the nervous system in general and the brain and cerebral cortex in particular have developed as adaptive mechanisms. To simplify grossly in order to make the point, the brain is the servant of the

stomach and the sex organs: Cognitive processes are instruments, means to an end.

One implication of the theme of this article is that the tables may have turned in the course of human evolution. Or at least the relation between master and servant has become more nearly symmetrical: The stomach exists, if you will, as much to nourish the brain as vice versa. Cognition is at times instrumental, and at other times an end in itself, with its own demands. Without adequate input, in the form of information, the cognitive system begins to deteriorate. To ward off cognitive malfunctioning, information-searching behavior is initiated in response to signals (boredom) analogous to hunger pangs, and so on, through the whole story of curiosity, information seeking, exploratory behavior, and the like.

To make the point in a somewhat different way, the brain is not like a computer, which will do its thing on demand and then sit silently until called on once again to perform. The brain, rather, is an instrument with needs of its own. And some of the processes that it mediates (that we loosely call "cognitive") may achieve states which are as demanding of *themselves* as are the organ systems that those processes were originally developed (through evolution) to serve. Indeed, as in the case of those self-destructive behaviors alluded to earlier, the demands of ideology may at times be utterly inimical to the demands of biology.

A Final Comment on Rationality

One of the aims of psychoanalytic psychotherapy, at least as Freud (1962) viewed it, is "to enable the ego to achieve a progressive conquest of the id [p. 46]." Thanks to Freud, and to many other pre- and post-Freudian writers—theologians, philosophers, psychiatrists, psychologists, novelists, playwrights—we have come to take for granted the position that evil is associated with the irrational and good with the rational. This assumption is nicely illustrated in a review of the book *Diana* (whose story was alluded to earlier) which contains the following sentence: "At some risk of oversimplification, it is nevertheless safe to say that in Diana Oughton, as in others, emotions came to rule the brain [Cooke, 1971, p. 35]." The reviewer may be right in that particular instance, but I would like to suggest the plausibility of just the opposite interpretation: Diana's ideology came to rule her emotions. More generally, I would call into question the easy assumption that the domi-

³ I wish to thank William J. McGuire, who offered this suggestion after innocently asking me, on a ride to the airport, what I was working on these days.

nance of behavior by rational, "cognitive" processes will necessarily assure personally and socially desirable outcomes. On the contrary, there may be as much to fear from unbridled ideation (especially in its extreme form, ideology) as there is from unconscious fantasies and impulses or unrestrained emotions.

Perhaps the point is that the domination of a complex system by any one of its components—even a "good" component—may lead to highly undesirable consequences. In the days of Watergate, when these words are being written, an obvious political analogy immediately comes to mind. In personality, as in politics, the safest, if not the most efficient, system is one with multiple components, or "institutions," that exist in some kind of tense equilibrium (id, ego, superego; Congress, President, Supreme Court). And perhaps to keep the system truly healthy there is need for additional external institutions (family, friends, therapist, society; a free press, other governments) keeping an objective eye out for its integrity and giving constructive feedback when the system seems to be getting out of balance.

Teaching Children to Read Using a Computer

RICHARD C. ATKINSON *Stanford University*¹

For the past 10 years I have existed in two quite separate worlds. One world is that of an experimental psychologist working in the isolation of a university laboratory on problems of memory and cognition; the other is that of an applied researcher attempting to computerize the instructional process. It would seem that there should be a fair amount of commerce between these two worlds, but I am disappointed to find that very few of my colleagues in memory and learning are aware of the work on computerized instruction, and this situation is equally true for my friends in education. Therefore, this article gives me an ideal opportunity to propagandize a bit for the potential that each of these fields has for the other.

This article is primarily descriptive, focusing on work that we have been doing at Stanford in teaching reading to first-, second-, and third-grade children. Let me emphasize, however, that there is a clear link between this work and basic research on memory and cognition. I like to refer to this link as a "theory of instruction." By that phrase I do not mean a highly formalized theory, but rather a loose collection of theoretical and empirical facts that can be used in conjunction with educational methods to design optimal procedures for instruction. Having written about the ingredients for a theory of instruction, I will not spend time on that topic here.² Simply stated, there are examples in which psychology provides powerful tools for devising optimal procedures, particularly when instruction can be brought under computer control. I will refer to several of these examples, but will discuss only two in detail.

Computer-Assisted Instruction and the Reading Curriculum

Our first efforts to teach reading under computer control were aimed at a total curriculum that would be virtually independent of the classroom teacher.³ These early efforts proved reasonably successful, but it soon became apparent that the cost of such a program would be prohibitive if applied on a large-scale basis. Further, it was shown that some aspects of instruction could be done very effectively using a computer, but that there were other tasks for which the computer did not have any advantages and possibly had some disadvantages over classroom teaching. Thus, during the last four or five years, our orientation has changed and the goal now is to develop low-cost computer-assisted instruction (CAI) that supplements classroom teaching and concentrates on those tasks in which individualization is critically important. A student terminal in the current program consists only of a Model-33 teletypewriter with an audio headset (see Figure 1). There is no graphic or photographic capability at the student terminal as there was in our first system, and the character set of the teletypewriter includes only uppercase letters. On the other hand, the audio system is extremely flexible and provides virtually instantaneous access to any one of 6,000 recorded words or messages.

The central computer which controls the CAI system is housed at Stanford University. Telephone lines link the computer to student terminals located in schools near the University and as far away as Florida, Oklahoma, Texas, and Washington, D.C. First-, second-, and third-grade students receive CAI reading instructions for anywhere from 15 to 30 minutes per day. Instruction begins with the student typing R for reading, an identification number, and his first name. The program responds with the student's last name and

Figure 1. Student running on the CAI reading program. (The terminal consists of a Model-33 teletypewriter and earphones with an audio amplifier. The program operates on a PDP-10 computer located at Stanford University and is connected remotely to terminals in the schools by multiplexed telephone lines. Although the terminal has no graphic capability, it is a sturdy, low-cost device that provides the student with a printed copy of his interaction with the instructional program.)

automatically transfers him to the point in the curriculum where he finished on the previous day.

Reading instruction can be divided into two basic tasks which have been referred to as *decoding* and *communication*. Decoding is the rapid, if not automatic, association of phonemes or phoneme groups with their respective graphic representations. Communication involves reading for meaning, aesthetic enjoyment, emphasis, and the like. Our CAI program provides instruction in both types of tasks, but focuses primarily on decoding. The program is divided into eight parts or strands. As indicated in Figure 2, entry into a strand is determined by the student's level of achievement in the other strands. Instruction begins in Strand O, which teaches the skills required to interact with the program. Entry into the other strands is dependent on the student's performance in earlier strands. For example, the letter identification strand starts with a subset of letters used in the earliest sight words. When a student reaches a point in the letter identification strand where he has exhibited mastery over the letters used in the first words of the sight-word strand, he enters that strand. Similarly, entry into the

spelling pattern strand and the phonics strand is controlled by the student's placement in the sight-word strand. On any given day a student may be seeing exercises drawn from as many as five strands. The dotted vertical lines in Figure 2 represent *maximal rate contours*, which control the student's progress in each strand relative to his progress in other strands. The rationale underlying these contours is that learning particular material in one strand facilitates learning in another strand; thus, the contours are constructed so that the student learns specific items from one strand in conjunction with specific items from other strands. In general, a student receives an amount of time in each strand proportional to the number of items yet to be completed in that strand before he reaches the next contour.

The CAI program is highly individualized so that a trace through the curriculum is unique for each student. The problem confronting the psychologist is to specify how a given subject's response history should be used to make instructional decisions. The approach that we have adopted is to develop simple mathematical models for the acquisition of the various skills in the cur-

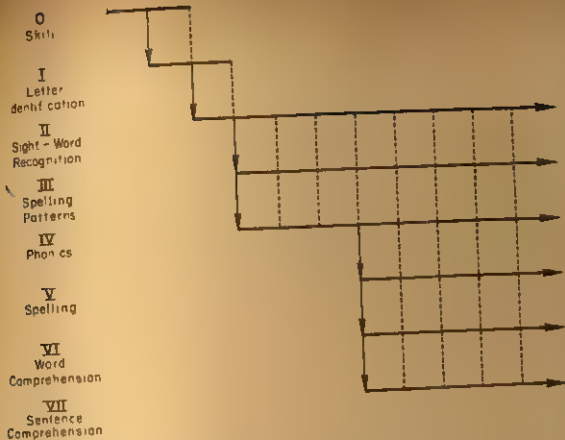

Figure 2. Schematic presentation of the strand structure. (Entry into each strand depends on a student's performance in earlier strands. The vertical dotted lines represent maximal rate contours which control the student's progress in each strand relative to the other strands.)

riculum and then use these models to specify optimal sequencing schemes. Basically, this problem is what has come to be known in the mathematical and engineering literature as *optimal control theory* or, more simply, *control theory*. The development of control theory has progressed at a phenomenal rate in the last decade, but most of the applications involve engineering or economic systems of one type or another. Precisely the same problems are posed in the area of instruction, except that the system to be controlled is the human learner rather than a machine or group of industries. If a model for the acquisition of a skill can be specified, then methods of control theory can be used to derive optimal instructional strategies.

I want to review some of the optimization procedures that have been developed, but in order for the reader to have some idea of how the CAI program operates, let me first describe a few of the simpler exercises used in Strands II, III, and IV.⁴ Strand II provides for the development of a sight-word vocabulary. Vocabulary items are presented in five exercise formats, but only the copy exercise and the recognition exercise will be described here. The top panel of Table 1 illustrates the copy exercise, and the lower panel illustrates the recognition exercise. Note in Table 1 that when a student makes an error, the system responds with

an audio message and prints out the correct response. In earlier versions of the program, the student was required to copy the correct response following an error. Experiments, however, demonstrated that the overt correction procedure was not effective and slowed down the pace of instruction; simply displaying the correct word following an error seems to be maximally effective.

Strand III provides practice with spelling patterns and emphasizes the regular grapheme-phoneme correspondences that exist in English. Table 2 illustrates exercises from this strand. For the exercise in the top panel of Table 2, the student is presented with three words involving the same spelling pattern and is required to select the correct one based on its initial letters. Once the student has learned to use the initial letter or letter sequence to distinguish between words, he then moves to the recall exercise illustrated in the bottom panel of Table 2. Here he works with a group of words, all involving the same spelling pattern. On each trial the audio system requests a word that requires adding an initial consonant or consonant cluster to the spelling pattern mastered in the preceding exercise. Whenever a student makes a correct response, a "+" sign is

printed on the teletypewriter. In addition, every so often the program will give an audio feedback message; these messages vary from simple ones like "great," "that's fabulous," "you're doing brilliantly," to some that have cheering, clapping, or bells ringing in the background. These messages are not generated at random, but depend on the student's performance on that particular day. If his performance is above that of the preceding three days, it will be so recognized with frequent audio messages.

When the student has mastered a specified number of words in the sight-word strand, he begins exercises in the phonics strand; this strand concentrates on initial and final consonants and consonant clusters in combination with medial vowels. As in most linguistically oriented curricula, students are not required to rehearse or identify consonant sounds in isolation. The emphasis is on patterns of vowels and consonants that bear regular correspondences to phonemes. The phonic strand is the most complicated one of the group and involves eight exercise formats; only two of the formats will be described here. The upper panel of Table 3 illustrates an exercise in which the student is required to identify the graphic representation of phonemes occurring at the end of words. Each trial begins with an audio presentation of a word that includes the phonemes, and the student is asked to identify the graphic representation. After mastering this exercise, he is then transferred to the exercise illustrated in the bottom panel of Table 3. The same phonemes are

presented, but now the student is requested to construct words by adding appropriate consonants.

Optimizing the Instructional Process

This has been a brief overview of some of the exercises used in the curriculum. The key to the curriculum is in the optimization schemes that control the sequencing of these exercises; these schemes can be classified at three levels. One level involves decision making within each strand. The problem is to decide which items to present for study, which exercise formats to present them in, and when to schedule review. A complete response history exists for each student, and this history is used to make trial-by-trial decisions regarding what instruction to present next. The second level of optimization deals with decisions about allocation of instruction time among the various strands for a given student. At the end of an instructional session, the student will have reached a certain point in each strand and a decision must be made as to the distribution of time among the strands in the next session. The third level of optimization deals with the distribution of instructional

time among students. The question here is to allocate computer time among students to achieve instructional objectives that are defined not for the individual student but for the class as a whole. In some global sense, these three levels of optimization should be integrated into a unified program. However, our understanding of these matters is still very incomplete, and we have been satisfied to work with each in isolation, hoping that later they can be incorporated into a single package.

I want to describe some aspects of optimization on the first level and then go into detail on an example from the third level. Problems at the second level were touched on earlier when I described the strand structure of the curriculum and the use of maximum-rate contours to allocate time among strands. In some respects, this optimization program is the most interesting of the group, but it cannot be explained without going into considerable detail.⁵

Optimization within a strand, what has been called Level 1, can be illustrated using the sight-word strand. The strand comprises a list of about 1,000 words; the words are ordered in terms of their frequency in the student's vocabulary, and words at the beginning of the list tend to have highly regular grapheme-phoneme correspondences. At any point in time, a student will be working on a limited pool of words from the list; the size of this working pool depends on the student's ability level and is usually between 5 and 10 words. When one of these words is mastered, it is deleted from the pool and replaced by the next word on the list or by a word due for review. Figure 3 presents a flow chart for the strand. Each word in the working pool is in one of five possible instructional states. A trial involves sampling a word from the working pool and presenting it in an appropriate exercise format. The student is pretested on a word the first few times it is presented in order to eliminate words already known. If he knows the word, he will pass criterion for the pretest and it will be dropped from the working pool. If the student does not pass the pretest, he first studies the word in a series of trials, using the copy exercise, and then in a series of trials using the recognition exercise. If review is required, he studies the word again in what is designated in Figure 3 as Exercises 4 and 5.

As indicated in the figure, a given word passes from one state to the next when it reaches criterion. And this presents the crux of the optimization problem, which is to define an appropriate criterion for each exercise. This has been done using simple mathematical models to describe the acquisition process for each exercise and the transfer functions that hold between exercises.⁶ Basically, these models are simple Markov processes that have been extensively investigated by learning theorists and are known to provide reasonably accurate accounts of performance on our tasks. Parameters of the models are defined as functions of two factors: (a) the ability of the particular student and (b) the difficulty of the particular word. An estimate of the student's ability is obtained by analyzing his response record on all previous words, and an estimate of a word's difficulty is obtained by analyzing performance on that particular word for all students ever run on the program. The student records are continually updated by the computer and are used whenever necessary to compute a maximum likelihood estimate of each student's ability factor and each word's difficulty factor.⁷ Given a well-defined model and estimates of its parameters, we can use the methods of control theory to define an optimal criterion for each exercise. The criterion will vary depending on the difficulty of the item, the student's ability level, and the precise sequence of correct and incorrect responses made by the student to the item. It is important to realize that the optimization scheme is not a simple one-stage branching program based on the last response, but rather depends, in a complicated way, on the student's complete response history.

Optimizing Class Performance

Now to turn to an example of optimization at what has been called Level 3. The effectiveness of the CAI program can be increased by optimally allocating instructional time among students. Suppose, for example, that a school has budgeted a fixed amount of time for CAI and must decide how to allocate that time among a class of first-grade students. For this example, maximizing the effective-

⁶ For a discussion of the learning models, see Atkinson and Paulson (1972); for a discussion of the transfer models, see Dear and Atkinson (1962).

⁷ See Atkinson and Paulson (1972) and Laubsch (1970) for a discussion of these methods.

⁵ See Chant and Atkinson (1973) for a discussion of the problem and applications.

tiveness of the CAI program is interpreted as meaning that we want to maximize student performance on a standardized reading test administered at the end of the first grade. Although other dependent measures can be used, this one provides a convenient benchmark against which to judge effectiveness.

On the basis of experimental data, the following equation has been derived that predicts performance on a standardized reading test as a function of the amount of time that a student spends on the CAI system:

$$P_i(t) = \alpha_i - (\alpha_i - \beta_i)e^{-\gamma_i t}$$

The equation predicts Student i 's performance on a standardized test as a function of the time, t , spent on the CAI system during the school year. The more time spent on the CAI program, the higher the level of achievement. The parameters α_i , β_i , and γ_i characterize Student i , and vary from one student to another. The parameters α_i and β_i are measures of Student i 's maximal and minimal levels of achievement, respectively, and γ_i is a rate of progress measure. These parameters can be estimated from scores on reading readiness tests and from the student's performance during his first hour of CAI. After estimates of these parameters have been made, the above equation can be used to predict end-of-the-year test scores as a function of the CAI time allocated to that student.

To summarize, it is assumed that a school has budgeted a fixed amount of time T on the CAI system for a first-grade class of N students; further, students have had reading readiness tests and a preliminary run on the CAI system so that estimates of the parameters α , β , and γ can be made for each student. The problem then is to allocate time T among the N students so as to optimize learning. In order to do this, it is first necessary to have a model of the learning process. Although the above equation does not offer a very detailed account of learning, it suffices as a model for purposes of this problem, giving all the information that is required. This is an important point to keep in mind. The nature of the specific optimization problem determines the level of complexity that needs to be represented in the learning model. For some optimization problems, the model must

provide a relatively complete account of learning in order to specify a viable strategy, but for other problems a simple descriptive equation often will suffice.

In addition to a model of the learning process, we must also specify our instructional objective. There are several objectives that seem reasonable, but only the following will be considered here:

A. Maximize the mean value of P over the class of students.

B. Minimize the variance of P over the class of students.

C. Maximize the mean value of P under the constraint that the resulting variance of P is less than or equal to the variance that would be obtained if no CAI were administered.

Objective A maximizes the gain for the class as a whole; Objective B reduces differences among students by making the class as homogeneous as possible; and Objective C attempts to maximize performance of the whole class, while insuring that differences among students are not amplified by CAI. To start, we will select Objective A as the instructional objective. If t_i is the time allocated to Student i , then the problem of deriving an optimal strategy reduces to maximizing the function

$$\phi(t_1, t_2, \dots, t_N) = \frac{1}{N} \sum_{i=1}^N [\alpha_i - (\alpha_i - \beta_i)e^{-\gamma_i t_i}]$$

subject to the constraint that $t_1 + t_2 + \dots + t_N = T$. This maximization can be done using the methods of dynamic programming. To illustrate the approach, computations were made for a first-grade class for which the parameters α , β , and γ had been estimated for each student. Employing these estimates, computations were carried out to determine the time allocations that maximized the above equation. For the optimal policy, the predicted mean performance level of the class on the end-of-the-year tests was 14% higher than a policy that allocated time equally among the students (i.e., a policy where $t_i = T/N$ for all students). This gain represents a substantial improvement; the drawback is that the class variance is roughly 15% greater than the variance for the class using an equal time policy. This means that if we are only interested in raising the class average, we

Figure 3. Partial flow chart for Strand II (sight-word recognition). (The various decisions represented in the bottom part of the chart are based on fairly complicated computations that make use of the student's response history.)

% gain in mean of P	14	-15	8
% gain in variance of P	15	-12	-6

Note. P is an end-of-the-year performance score on a standardized reading test. In general, a policy that leads to a positive gain in the mean and a negative gain in variance is preferable.

will have to give the rapid learners substantial time on the CAI system and let them progress far beyond the slow learners.

Although a time allocation that complies with Objective A did increase overall class performance, the correlated increase in variance suggests that other objectives need to be considered. For comparison, time allocations also were computed for Objectives B and C. Table 4 presents the predicted gain in average class performance as a percentage of the mean value for the equal time policy. Objective B yielded a negative gain, and so it should, since its goal was to reduce variability, which is accomplished by holding back on rapid learners and giving a lot of attention to the slower ones. The reduction in variability for Objective B is 12%. Objective C, which strikes a balance between Objective A, on the one hand, and Objective B, on the other, yields an 8% gain in average performance and yet reduces variability by 6%.

In view of these results, Objective C seems to be the preferred one. It offers a substantial increase in average class performance while maintaining a low level of variability. These computations make it clear that the selection of an instructional objective should not be done in isolation but should involve a comparative analysis of several objectives, taking into account more than one dimension of performance. Even if the principal goal is to maximize the class average, it is inappropriate in most educational situations to select Objective A over C if it is only slightly better for the class average, while permitting variability to mushroom.

Effectiveness and Costs

Next, I want to make a few remarks about evaluation studies and the costs of the CAI program.

Several evaluation studies have been conducted in the last few years, and yet another now is being done by the Educational Testing Service. Rather than merely review these studies, I would like to describe one in some detail.⁸ In this particular study, 50 pairs of kindergarten students were matched on a number of variables, including sex and reading readiness scores. At the start of the first grade, one member of each pair was assigned to the experimental group and the other to the control group. Students in the experimental group received CAI, but only during the first grade; students in the control group received no CAI. The CAI lasted approximately 15 minutes per day; during this period the control group studied reading in the classroom. Except for this 15-minute period, the school day for the CAI group was like that of the control group. Standardized tests were administered at the end of the first grade and again at the end of the second grade. All the tests showed roughly the same pattern of results; to summarize the findings, only data from the California Cooperative Primary Reading Test will be described. At the end of the first grade, the experimental group showed a 5.05-month gain over the control group. The groups, when tested a year later (with no intervening CAI treatment), showed a difference of 4.90 months. Thus, the initial difference observed following one year of CAI was maintained, although not amplified, during the second year when no CAI was administered.

An interesting aspect of these results is that the boys appeared to benefit more from CAI than the girls. On all reading tests used in the evaluation, the girls as a group were superior to the boys. However, for the control group, the magnitude of the difference between boys and girls was greater than for the experimental group. For example, on the California Cooperative Primary Reading Test, the relative improvement for boys in the experimental group versus those in the control group was 42%; the corresponding figure for girls was 17%. These data suggest that both boys and girls benefit from CAI instruction, but that the gain is greater for boys. This observation is not unique to this study, but replicates a result from one of our earlier studies.⁹ It is a common finding in

⁸ For a detailed account of this study, see Fletcher and Atkinson (1972).

⁹ See Atkinson (1968a) for a review of earlier studies.

research on reading that girls perform better than boys. This sex difference has been attributed at least in part to the social organization of the classroom and the predominance of female teachers. It is also argued that first-grade girls are more facile in memorization than boys and that this ability further aids the girls in curricula that emphasize sight-word procedures. If these two arguments are correct, then one would expect that placing the students in a CAI environment and using a curriculum that emphasizes analytic skills would reduce sex differences in reading. Our data tend to support this line of argument.

The results obtained in this and other studies can be used to project performance through the third grade. I will not explain the formula used to make the projection but will simply state the conclusion. For the population of students with which we have worked, the average reading level at the end of the third grade is approximately 2.9 when CAI is not used. For students who receive CAI, the grade level is 4.1. These values are to be compared with a national norm of 4.0. Thus, students with CAI are slightly above grade level by the end of the third grade, while those without CAI are about one year behind.

Can CAI be cost effective? The cost of daily sessions on our system is about \$.55 per student. Based on a school year of 176 days, the yearly cost is roughly \$97.00 per student. If this is multiplied by three, we have a figure of \$291.00, a cost that places students at grade level by the end of the third grade who would normally be over a year behind. There is no doubt that such a cost is acceptable if future evaluations are as promising as they have been to date.¹⁰

Conclusion

In my view, individualizing instruction is the key factor in successfully teaching reading. This does not mean that all phases of instruction should be individualized, but often certain skills can be mastered only if instruction is sensitive to the student's particular difficulties. A teacher interacting on a one-to-one basis with a student may well be more effective than a CAI program. However, when working with a group of children (even as few as four or five), it is unlikely that she can match the

computer's effectiveness over an extended period of time.

The possibilities for developing optimal instructional procedures are, of course, most promising at the elementary school level. In areas like initial reading and primary grade mathematics, we have an adequate understanding of many of the psychological processes involved. Simple models can be formulated to describe these processes, and in turn be used to derive optimal procedures. However, we know very little about the cognitive processes that underlie mastering a college-level curriculum in fields such as sociology or philosophy. In these cases, we cannot formulate models that describe learning, and thus cannot use the methods of optimization discussed here. However, more can be done at the college level than one might expect based on current work. Certainly, models can be developed for some aspects of learning in the natural sciences and second-language acquisition, even if these models are little more than descriptive equations. Research needs to be done to determine the feasibility of the approach, and much can be learned by experimenting with alternative optimization schemes, however loosely they may be related to formal models. Finding optimization schemes that work can tell us about the nature of the learning process and provide direction for theoretical analysis. A two-way exchange between the formulation of optimization procedures and development of descriptive models has not played as significant a role in psychological research as it merits.

In this discussion, I have tried to indicate some of the issues that arise in constructing a CAI program. From a broader perspective, the problem that we face in developing curricula is twofold. One aspect of the problem is to invent effective exercises for teaching particular skills and concepts; the other is to devise schemes for sequencing among these exercises. The problem of inventing and evaluating instructional exercises is an old one in psychology. There is no question that we know how to carry out the kinds of experiments needed for establishing the effectiveness of an instructional procedure. But the problem of formulating a scheme for sequencing among instructional procedures that is sensitive to the student's current state of knowledge is another matter, and one that has received very little investigation. Before the advent of the computer there was no real flexibility in manipulating the flow of instruction in a school situation; therefore, whether

¹⁰ For a more detailed discussion of cost effectiveness, see Jamison, Fletcher, Suppes, and Atkinson (1974).

or not we understood how to individualize learning was of limited consequence. Now, with the computer, a new dimension of school learning has emerged. It is my belief that psychology's potential contributions in this area are of great practical significance. The development of a viable theory of instruction may be the most important issue facing psychology, and one that can revolutionize our conceptions of how man thinks and learns.

Psychological Environments

Expanding the Scope of Human Ecology

PAUL M. INSEL *Stanford University*

RUDOLF H. MOOS *Stanford University*¹

Like people, environments have unique personalities. Just as it is possible to characterize a person's "personality," environments can be similarly portrayed with a great deal of accuracy and detail. Some people are supportive; likewise, some environments are supportive. Some men feel the need to control others; similarly, some environments are extremely controlling. Order and structure are important to many people; correspondingly, many environments emphasize regularity, system, and order.

Henry Murray (1938) first conceptualized the dual process of personal needs and environmental press. He suggested that individuals have specific needs, the strength of which characterizes "personality." The environment potentially satisfies or frustrates these needs. Murray's model for studying behavior thus consisted of the interaction between personality needs and environmental press. Murray's concept of needs provided a point of entry for the development of a variety of measurement instruments to study personality; however, no parallel development in the objective measurement of environmental press was attempted until much later.

Stern, Stein, and Bloom (1956) expanded Murray's contribution. They demonstrated that behavior could be predicted much better when the setting in which the behavior occurred was clearly defined so as to include the social demands of the situation. Pace and Stern (1958) developed the concept of environmental press further by applying the logic of "perceived climate" to the study of "atmosphere"

at universities and colleges. They constructed the College Characteristics Index (CCI) which measured the global college environment by asking students to act as reporters. Specifically, students were asked to answer true or false to items covering a wide range of topics about their college, such as student-faculty relationship, rules and regulations, classroom methods, facilities, etc. The general logic of this approach suggests that the consensus of students' characterizing their college environment constitutes a measure of environmental climate, and that this environmental climate exerts a directional influence on their behavior.

Thus, one might infer a general principle to the effect that the way one perceives his surroundings or environment influences the way one will behave in that environment. While this principle has a commonsense ring to it, it is not usually applied in a practical way to the routine problems and tasks with which psychologists deal. For example, personality and projective tests are frequently administered and interpreted with the assumption that results will portray permanent and enduring qualities that transcend the environment, providing information that can accurately predict behavior regardless of the setting in which the behavior is likely to take place. This assumption is pervasive in spite of much evidence showing that properties of the environment may account for more of the variance in behavior than measures of trait qualities or even biographic and demographic background data (Douglas, 1964; Mischel, 1968; Wolfe, 1966). For example, Friedlander and Greenberg (1971) studied the job performance and retention of 478 hard-core unemployed workers and found that the sole correlate of their work effectiveness and ability to retain jobs was the extent to which they perceived their work environment to be supportive. Personality and background data were found to be unrelated to work effectiveness and job retention.

Classifying Human Environments

The concept of environment has historically been somewhat ambiguous and amorphous. Formal and systematic study of environments is rooted in the biological sciences where the term *ecology* is most commonly applied to the natural habitats of animals. *Human ecology* is a more recent term extending to the domain of geographers and sociologists who are interested in the distributions of human populations. The term *social ecology* has evolved mainly from the efforts of psychologists and other behavioral scientists to direct their inquiries toward a more complete view of man interacting with both his physical and social environment (Moos & Insel, 1974).

The seeds of social ecology can be found in both ecology and human ecology. Because ecological phenomena may be considered as existing over the entire range of organisms and at a number of different levels of organization, the field of ecology has become fractionated and specialized.

Human ecology departs from animal and plant ecology in the nature of its regulatory mechanisms. Among the special regulatory mechanisms which operate in a human society are public opinion, punishment, rewards, competition, and supply and demand. Social cooperation is perhaps the most important regulatory mechanism in society, serving to mitigate the destructive and predatory elements found in the ecological evolution of other animal communities. Knowledge about the operation of the regulatory mechanisms which keep human societies in balance with the resources of their milieus is one of the concerns of social ecology.

The emerging discipline of social ecology grows out of this interaction of man with his environment. To this extent it transcends human ecology. It reflects the traditional concerns of ecology both in its emphasis on the measurement of objective physical characteristics of environments (e.g., temperatures, rainfall, air pollution, noise levels; the shapes, sizes, and physical arrangements of buildings) and in its inquiry into the short-term evolutionary and adaptive consequences of these environments. Social ecology, however, expands these concerns by systematically dealing with the social environment and its interaction with the physical milieu. And, unlike ecology and human ecology, social ecology has an explicit value orientation in that it is concerned with promoting maximally effective human functioning. Finally, social ecology touches the main currents of scientific thought in psychiatry, medicine, and epidemiology in its special emphasis

on the identification of maladaptive responses and their relationship to environmental variables.

Moos (1973a) suggested six different ways of conceptualizing human environments:

1. *Ecological dimensions.* These include (a) meteorological and geographical variables (this view of the environment suggests that society has been shaped by climate, topography, and other geographical features of inhabited regions), and (b) physical design variables. Here man's behavior is influenced by architecture and physical constraints which limit or even define the range of activities in which man can be involved.

2. *Dimensions of organization structure.* This view of the environment suggests that behavior is influenced by structural dimensions such as size, staffing ratios, salary levels, span of organizational control, etc.

3. *Personal characteristics of milieu inhabitants.* This view implies that the character of an environment depends on the nature of its members and that the dominant features of an environment depend on the typical characteristics of its members, such as age, sex, socioeconomic status, abilities, group memberships, physique, and other background data.

4. *Behavior settings.* This view of the environment originated with Roger Barker (1968), who emphasized the importance of studying behavior settings as natural phenomena. Behavior settings are conceptualized as ecological units which have both an environmental and a behavioral component.

5. *Functional or reinforcement properties of environments.* This view of the environment suggests that people vary their behavior substantially from one setting to another as a function of the reinforcement consequences for particular behaviors.

6. *Psychosocial characteristics and organizational climate.* This conceptualization encompasses both psychological and social dimensions of the environment in a framework of person-milieu interaction. The approach accommodates both an inside perception of what the environment is like as well as an outside observer's impression, although most of the work to date emphasizes the importance of climate as perceived by participating members of the environment.

Measuring Environments

As suggested earlier, a limited literature exists on the development of systematic approaches to measuring environments. This is partly because

"environments" are unwieldy and thus difficult to deal with as objects of investigation. This problem has been partially resolved by such investigators as Barker (1968), who focused on specific environmental units which have both a space and a time locus, and Moos (1969), who focused on subenvironments or subunits in which milieu occupants interact with each other on some regular and familiar basis.

Moos and his associates at the Social Ecology Laboratory at Stanford University have made substantial contributions toward developing an in-depth program of characterizing and assessing the psychosocial qualities of environments. They have extensively studied eight different environments and have developed perceived climate scales for each environment: (a) psychiatric wards; (b) community-oriented psychiatric treatment programs; (c) correctional institutions; (d) military basic training companies; (e) university student residences; (f) junior and senior high school classrooms; (g) work environments; (h) social, therapeutic, and decision-making groups.

Underlying Patterns of Differing Environments

Common dimensions have emerged from studies of the eight different kinds of environments. These have been conceptualized by Moos (1974d) in three broad categories: relationship dimensions, personal development or goal orientation dimensions, and system maintenance and change dimensions. These dimensions are similar across the eight environments mentioned although vastly different settings may impose unique variations within the general categories.

RELATIONSHIP DIMENSIONS

Relationship dimensions identify the nature and intensity of personal relationships within the environment. They assess the extent to which individuals are involved in the environment and the extent to which they support and help each other. As can be seen in Table 1, examples of relevant subscales in the eight climate scales are involvement, affiliation, staff support, peer cohesion, and spontaneity.

Personal development dimensions consider the potential or opportunity in the environment for personal growth and the development of self-esteem. The precise nature of personal development dimensions varies somewhat among different environments

and depends mainly on the goals of a particular environment. Examples of relevant subscales are autonomy, practical orientation, competition, and intellectuality.

System maintenance and system change dimensions assess the extent to which the environment is orderly and clear in its expectations, maintains control, and is responsive to change. Examples of the subscales one finds here are order and organization, clarity, control, and innovation. The three "basic" categories can best be seen as they fit into the framework of the four environments shown in Table 1.

The eight climate scales mentioned earlier can be classified into one of four types of environments: (a) treatment environments, (b) total institutions,² (c) educational environments, and (d) community environments. Treatment environment measures are the Ward Atmosphere Scale (Moos, 1974d) and the Community-Oriented Programs Environment Scale (Moos, 1974a). Total institutions environment measures are the Correctional Institutions Environment Scale (Moos, 1974b) and the Military Company Environment Inventory (Moos, 1973b). Educational environment measures are the University Residence Environment Scale (Moos & Gerst, 1974) and the Classroom Environment Scale (Moos & Trickett, 1974). Community environment measures include the Work Environment Scale (Insel & Moos, 1972) and the Group Environment Scale (Moos & Humphrey, 1973). A final technique, the Family Environment Scale, is being developed.

To give an example of the similarity of differing environments, let us compare the social environment of a psychiatric ward with the social environment of a factory. On the surface these two environments appear rather remote from each other. They have much in common, however. The instruments used to assess these two settings were the Ward Atmosphere Scale (WAS) and the Work Environment Scale (WES). The relevant relationship dimensions on the WAS are involvement, sup-

² Goffman (1961) suggested that "total institutions" take over the life processes of persons who live within their physical constraints. They differ from other environments in that they require large groups of unselected members to conduct their lives in a similar fashion and on a fixed schedule. These developing life-styles are purportedly designed to fulfill the aims of the institutions. Total institutions have two distinct groups of inhabitants: staff and inmates. These two groups interact on a restricted, often formally prescribed, basis. Goffman suggested that two different social and cultural worlds develop, which move alongside one another but have minimal contact.

TABLE 1

Similarities of Social Climate Dimensions across Environments

Type of dimension	Treatment environment		Total environment		Educational environment		Community environment	
	Ward Atmosphere Scale	Community-Oriented Programs Environment Scale	Correctional Institutions Environment Scale	Military Company Environment Inventory	University Residence Environment Scale	Classroom Environment Inventory	Work Environment Inventory	Group Environment Inventory
Relationship								
Involvement-affiliation	X	X	X	X	X	XX	X	
Spontaneity-expressiveness	X	X	X					X
Support	X	X	X	X	X	X	X	XX
Cohesiveness				X			X	X
Personal development								
Autonomy-independence (personal status)	X	X	X	X	X		X	X
Practical orientation (task orientation, academic achievement)	X	X	X		X	X	X	X
Personal problem orientation (self-discovery)	X	X	X					X
Anger and aggression	X	X						X
Competition					X	X		
Intellectuality					X			
Traditional social orientation					X			
System maintenance and system change								
Order and organization	X	X	X	X	X	X		X
Clarity	X	X	X	X		X		X
Control	X	X	X	X		X	X	X
Physical comfort							X	
Work pressure							X	
Innovation-student influence					XX	X	X	X

port, and spontaneity. Relationship dimensions on the WES are involvement, staff support, and peer cohesion. Program involvement on a psychiatric ward refers to how active and energetic patients are in the day-to-day functioning of the ward. Involvement in a factory setting refers to the extent to which workers are concerned and committed to their jobs. Support on a psychiatric ward indicates the extent to which patients are encouraged to be helpful and supportive toward other patients and how supportive the staff is toward patients. Staff support in a factory indicates the extent to which management is supportive of workers and encourages workers to be supportive of each other. The subscales of involvement and support are roughly equivalent in both settings. Spontaneity, however, is more relevant to a treatment or therapeutic environment in which people are often encouraged to

act openly and to freely express their feelings. This aspect of the climate in a factory setting can be seen more appropriately as part of both the staff support and peer cohesion components. On a psychiatric ward, staff support and peer support are one dimension since they correlate so highly with one another. But in a factory setting they are independent.

As mentioned earlier, some environments possess more than one aspect of the same property. For example, work environments have two distinctly different support elements. One element is called *peer cohesion* and accounts for the social and interpersonal relationships that develop among workers and their tendency to stick together and help each other. The second element, called *staff support*, accounts for the degree of friendship and communication between management and nonmanagement

personnel and the extent to which management encourages and helps nonmanagement personnel. These two elements identify a distinction between peer support and supervisor or staff support. In psychiatric and correctional environments, peer support tends to merge with staff support. In fact, it is difficult to find programs where these two support variables are not correlated positively. However, in a work environment, nonmanagement personnel frequently spend a great deal of time together maintaining a separate factor of cohesiveness.

PERSONAL DEVELOPMENT

The second category is personal development. Both settings have two subscales in common, namely, autonomy and practical or task orientation. Autonomy on a psychiatric ward involves how independent and self-sufficient patients are encouraged to be in making their own decisions about their personal affairs. For example, can a patient wear what he wants? Can he leave the ward without permission? In a factory setting, the issues are similar in that they are related to personal growth and independence. For example, are employees encouraged to learn more than one job? Can employees use their own initiative to do things?

The second subscale on a psychiatric ward is practical orientation. This component looks at the extent to which the patient's environment orients him toward preparing himself for release from the hospital. Such things as training for new jobs and setting and working toward goals are considered. In a factory the component of task orientation accounts for the extent to which the environment emphasizes good planning and efficiency and encourages workers to "get the job done."

SYSTEM MAINTENANCE

The third category for comparison is system maintenance, in which there are two identical subscales for both psychiatric ward and factory environments. These subscales are clarity and control. Clarity accounts for the extent to which both patients and workers know what to expect in their daily routines and how explicitly rules and policies are communicated. For example, do patients know when doctors will be on the ward? If a patient's medicine is changed, does a nurse or doctor tell him why? In a factory, do employees know when supervisors will be available? Do employees

know who to see when a problem arises? The second component, control, refers to the extent to which staff or supervisors use measures to keep patients or workers under control. On a psychiatric ward, can patients call nursing staff by their first names? In a factory, can employees be absent from work without an authorized or written explanation?

The foregoing hopefully conveys the similar threads that make up the fabric of remotely related environments. The importance of these threads can be seen more clearly in a situation in which a patient is discharged from a psychiatric ward and gains employment in a factory setting. Perhaps diagnostic work-ups could benefit from this type of "total milieu" approach. For example, instead of administering the MMPI or Rorschach and trying to predict from these tests what the most suitable treatment might be for the patient, the psychologist might ask the patient to respond to the ideal form of the Ward Atmosphere Scale. If the patient indicates his need for more support or more order on the WAS, the psychologist would then be in an advantageous position in recommending a ward that had a climate that emphasized support and order. The same approach might be used in a work setting if the climate of the work environment was known.

The three basic dimensions (relationship, personal development, and system maintenance) identified in treatment environments are also found in total institutions and educational and community environments. However, some environments have a unique component within a particular category which is peculiar to them. For example, work pressure is specifically and solely relevant to work environments where things like time pressure, deadlines, strain, urgency, and speed may dominate the job milieu. Another example, falling within the personal development category, is "traditional social orientation," a subscale on the University Residence Environment Scale (URES). This variable accounts for the emphasis on dating, going to parties, and other traditional heterosexual interactions that one finds in student housing programs.

The eight social climate scales discussed earlier were all developed at the Social Ecology Laboratory at Stanford University. Can relationship, personal development, and system maintenance and system change variables be identified in other organizational climate scales? The results of eight different investigators are utilized and summarized in Table 2.

TABLE 2

Dimensions of Organizational Climate Scales

Scale	Relationship	Personal development	System maintenance and system change
Organizational Climate Index (Stern, 1970)	Closeness, group life	Intellectual climate, personal dignity, achievement standards	Orderliness, impulse control (constraint)
College and University Environment Scale (Pace, 1969)	Community	Awareness, scholarship	Practicality, propriety
Institutional Functioning Inventory (Peterson, 1970)	Institutional esprit	Intellectual-aesthetic, extracurriculum, concern for improvement of society, concern for undergraduate learning, concern for advancing knowledge, meeting local needs	Freedom, democratic governance, self-study and planning, concern for innovation, human diversity
Learning Environment Inventory (Walberg, 1969)	Intimacy, friction, cliqueness, apathy, favoritism	Difficulty, speed	Formality, goal direction, democratic, disorganization, diversity
Organizational Climate Description Questionnaire (Halpin & Croft, 1963)	Esprit, intimacy, consideration, disengagement	Thrust, hindrance	Production emphasis, aloofness
Agency Climate Questionnaire (Schneider & Bartlett, 1970)	Managerial support, intraagency conflict, new employee concern	Agent independence	Managerial structure
Climate Questionnaire (Litwin & Stringer, 1968)	Warmth, support, conflict, identity	Responsibility, risk, standards, reward	Structure
Dimensions of Group Processes (Fairweather, 1969)	Group cohesiveness	Group performance	Leadership and role delineation

The basic logic and conceptualization appears to be consistent with the scales of other investigators. For example, the College and University Environment Scale (Pace, 1969) has five subscales: (a) *community* describes a friendly, cohesive group-oriented campus and is clearly a relationship dimension; (b) *awareness* describes a concern about personal, poetic, and political meaning, self-understanding and reflectiveness and is clearly a personal development dimension; (c) *scholar* describes an environment characterized by intellectuality, scholastic discipline, and academic achievement and is also clearly a personal development dimension; (d) *propriety* describes an environment that is polite,

considerate, mannerly, proper, and conventional and where group standards of decorum are important. To the extent to which this variable emphasizes order and clarity within the environment it belongs in the category of system maintenance; (e) *practicality* describes an environment characterized by organization, enterprise, material benefits, and social activities. This is also a system maintenance dimension, since its essential aspect reflects orderly supervision and organization.

The second test reviewed is the Institutional Functioning Inventory (Peterson, Centra, Hartnett, & Linn, 1970). This instrument also lends itself to studying colleges and universities and pro-

vides 11 variables judged to be important in American higher education. Institutional esprit is clearly a relationship dimension. The following belong to the dimension of system maintenance and system change: freedom (lack of restraint on academic or personal life), democratic governance (extent of opportunity for participation in decision making), self-study and planning (emphasis on continuous long-range planning for the total institution), concern for innovation (commitment to experimentation with new ideas for educational practice), and human diversity (heterogeneity of faculty and student body in background and attitudes). The emphasis of these variables is on system change, which generally tends to be more strongly prevalent in most university environments than is system maintenance. Finally, the other five variables belong to the personal development dimension, that is, intellectual-aesthetic extracurricular interests (availability of activities and opportunities for intellectual and aesthetic stimulation outside the classroom), concern for improvement of society, concern for undergraduate learning, concern for advancing knowledge, and meeting local needs (emphasis on providing educational and cultural opportunities for adults in the surrounding area).

Table 2 indicates subscales for two other organizational climate scales relevant to educational environments, that is, the Learning Environment Inventory (Walberg, 1969) and the Organizational Climate Description Questionnaire (Halpin & Croft, 1963). The elements identified by these two scales can be conceptualized as falling within the three basic categories.

From results based on both educational and industrial environments, Stern (1970) identified two major types of second-order factor dimensions using the Organizational Climate Index (OCI). He indicated that the OCI factor structure essentially replicates his former scale, the CCI. Stern reported that the OCI has been factored three times. One analysis was based on the responses of teachers in elementary, junior high, and senior high schools; a second on Peace Corps trainees; and a third on technicians employed in three different industrial sites. Six factors were extracted in a first-order analysis and two in a second-order analysis. Stern (1970) summarized his results as follows:

The first of the second-order factors describes a variety of press for facilitating growth and self-enhancement; the other reflects organizational stability and bureaucratic self-maintenance. These tend to confirm the hypothesized distinction drawn earlier between anabolic and catabolic press [p. 68].

Stern did not explicitly make a distinction between relationship and personal development dimensions. He also did not include system change dimensions in his category of control or system maintenance press. On the other hand, two variables which appear to be relationship dimensions were identified by Stern as closeness and group life. Three of Stern's variables appear to reflect personal development. He called these intellectual climate, personal dignity, and achievement standards. Stern's last two system maintenance factors are labeled orderliness and impulse control.

Stern's conceptualization is based on factor solutions and closely coincides with our conceptualization, strongly supporting the notion that there is a limited number of underlying patterns which can characterize a rather large and varied group of social environments.

Two more examples (Table 2) show similar conceptualizations. The Agency Climate Questionnaire (Schneider & Bartlett, 1970) and the Climate Questionnaire (Litwin & Stringer, 1968) were both constructed to assess industrial environments. The ACQ is primarily for insurance agencies and has subscales such as (a) managerial support (managers take an active interest in agents as individuals), (b) managerial structure (managers require that agents adhere strictly to budgets), and (c) agent independence (agents receive an accurate picture of job potential when they are contacted). Some of the Litwin and Stringer dimensions are (a) warmth (the feeling of general good fellowship that prevails in a work group atmosphere), (b) support (the perceived helpfulness of the managers and other employees in the group), (c) identity (the feeling that the employee belongs to the company and is a valuable member of a working team), (d) responsibility (the feeling of being one's own boss and not having to double check all of one's decisions), (e) risk (the sense of riskiness and challenge in the job and in the organization), and (f) structure (the feeling that the employees have about the constraints of the groups in terms of rules and regulations). Both scales are strikingly similar in basic dimensions to those identified by the Social Ecology Laboratory in very different environments.

Finally, an example is provided by an assessment of group processes conducted by Fairweather, Sanders, Cressler, and Maynard (1969) in which they compared a ward-based with a community-based psychiatric treatment program. They found three dimensions which characterized group processes and labeled these dimensions (a) group cohesiveness

(cohesiveness, morale, attraction to group, satisfaction with leader), (b) group performance (performance, reward, problem input, information input), (c) leadership and role delineation (leadership, role clarity).

One may conclude from the work in this area that relationship, personal development, and system maintenance and system change dimensions must all be accounted for in order for an adequate and reasonably complete picture of the environment to emerge.

Environmental Impact on Individual Functioning

The study and assessment of environments are important because of their relevance to individual functioning. The "climate" of environments in which people function relates to their satisfaction, mood, and self-esteem and to their personal growth. Environments shape adaptive potentials as well as facilitate or inhibit initiatives and coping behavior. For example, environments that place an emphasis on relationship dimensions such as involvement and support usually have high morale (Cumming & Cumming, 1962). It has been demonstrated that psychiatric wards and correctional units that emphasize autonomy and personal problem orientation have patients and residents who like the staff and feel they can develop their abilities and increase their self-confidence (Moos, 1974c).

Social environments also have significant impact on more objective criteria of behavioral outcome. For example, Moos, Shelton, and Petty (1973) related the social environment of psychiatric wards to objective indexes of treatment outcome as assessed by dropout rates (how many patients left the ward before treatment was completed), release rates (how rapidly were patients released from the ward), and community tenure (how long patients were able to stay in the community after release from the hospital). Two independent studies found that patients and staff perceived wards that had high dropout rates to be low in involvement, support, order and organization, and program clarity. Wards with high release rates were perceived as strongly emphasizing practical orientation, but inclined toward "unexpressiveness," whereas wards that kept patients out of the hospital longest were perceived as emphasizing autonomy, a practical orientation, order and organization, and the open expression of feelings, particularly angry feelings.

Similar results can be seen in the environment of military basic training companies. Moos (1973d) found that military company "climate" was related to important indexes of outcome, such as total performance on graded tests at the end of basic training, the AWOL (absent without official leave) rate, and the rate of sick call. Companies which did best on total performance criteria were those that emphasized both peer cohesion and officer support. Companies with excessive sick call lists contained men who felt that the work was repetitious and boring, that there was no opportunity for leadership roles and no orientation to the company, and that they were ridiculed in front of others. Company environments had effects on men's moods. For example, companies with high scores on officer control and low scores on personal status had men who felt more anxious. Companies high on officer control and low on peer cohesion had men who felt more depressed. Companies high on officer control and low on both officer support and clarity had men who felt more hostility. Thus, one finds specific relationships between dimensions of basic training company environments and types of negative effects.

Stressful environments have been shown to have cumulative long-term effects on those who function within them. Caffrey (1969) studied the environments of Benedictine and Trappist monks and found a prevalence of coronary heart disease in those environments characterized as competitive with a sense of time urgency. Sales (1969) suggested in his review that environments with work overload are implicated as precursors of cardiovascular disease.

In an extensive review of the literature, Kirtz and Moos (in press) concluded that the evidence supports the hypothesis that "social environmental factors have pronounced effects on human physiological processes." They suggested that

the social stimuli associated with the relationship dimensions of *support*, *cohesion* and *affiliation* generally have positive effects—enhancing normal development and reducing recovery time from illness, for example. Goal Orientation and System Change dimensions such as *responsibility*, *work pressure*, and *change* can increase the likelihood of stress and disease.

Toward an Optimum Environment

What are the criteria by which environment can be judged as favorable? Lewis Mumford (1968) viewed an ideal environment as "seeking continuity, variety, orderly and purposeful growth" as opposed

to an environment that "magnifies authoritarian power and minimizes or destroys human initiative, self-direction, and self-government [p. 221]." Mumford suggested that optimum environments are organic and the qualities that make them desirable have to do with people, not "machines."

There are, of course, no clear, well-defined criteria for an ideal environment that can meet everyone's requirements. Inhabitants of specific environments would undoubtedly have different criteria and different goals. The point is, however, that the likelihood of achieving an optimum environment is greatly facilitated when critical decisions about changing the environment are in the hands of the people who function within the environment. For an outsider to impose the kind of order and structure according to his own unique view of "Utopia" would undoubtedly result in strong resistance which can manifest itself in many subtle and disguised ways.

Moos (1974c) has presented a methodology for facilitating social change which is particularly relevant to small environments that have a moderate to high frequency of interactions among milieu members. The approach has four basic components:

1. Everyone involved in the environment is given the opportunity to report his view of how the current environment is functioning on the relevant dimensions discussed earlier. In addition, all participants are asked to convey information about their conceptualizations of an ideal social system. Thus, the goals and general value orientations of the milieu occupants are systematically assessed.
2. Individualized feedback is then given on the results of these assessments. Particular attention is paid to similarities and differences in the perceptions of various important groups within the environment; for example, in a hospital setting: patients versus doctors and nurses; in an industrial setting: workers versus management; in a classroom: students versus teachers. In addition, emphasis is placed on the similarities and differences between the "real" and the "ideal" social environment and the subsequent implications for change.
3. Practical planning of specific methods by which change might occur along specified dimensions is then instituted. This planning is usually done with the help of a social systems change "facilitator" who is experienced in the ways in which different types of social systems can change.
4. The change process itself is assessed by one or more reassessments of the characteristics of the

social environment. These results are continuously fed back to the participants providing an ongoing, systematic approach to achieving the kind of environment participants would like to have.

This methodology is linked with concepts of problem-solving, coping, and adaptive behavior. Many theorists have discussed each individual's active need for involvement and for the prediction and control over his own environment (White, 1959). The active propensities of man as scientist of different aspects of stimulation and variety-seeking motivation and of the importance of cognition and information seeking are central to planning effective social change methods. This approach is consistent with these important needs which include actively helping to mold one's social environment in desired directions. Its use may even help some individuals achieve a new competence, that of being able to change and control their own environment.

Validity in Personality Trait Attribution

JOHN GORMLY *Rutgers—The State University*

WALTER EDELBERG *Rutgers—The State University*¹

A fundamental assumption underlying the assessment of personality traits is that people have some generalized ways of behaving that can be observed across a variety of situations. The large number of research articles, graduate courses, and textbooks dealing with the assessment of personality traits illustrates that many individuals are proceeding as if this fundamental assumption were true.

Mischel (1968), in a very considered way, argued that personality traits are constructs of the *observer*, which may have little or nothing to do with generalized behavior patterns of the observed. He reviewed data which showed that the structure of personality traits which come from trait ratings of peers can be duplicated by people rating others after being in the same room for less than 15 minutes (Passini & Norman, 1966). These data, of course, are not definitive in supporting Michel's position with respect to the behavioral validity of traits² (Wiggins, 1973); nevertheless, Michel's review of the personality assessment literature clearly announces that data are sorely lacking that would definitively support the notion that personality traits are components of a person's behavior which are consistent across situations.

Mischel summarized data which indicate that stability in behavior is highest for intellectual and cognitive variables, where the situations used in eliciting the behavior have a high degree of similarity. Investigations of the cross-situational stability of social behavior, however, most frequently reveal a low degree of stability from situation to

situation; this is in sharp contrast with expectations from the trait viewpoint. The disconfirming data for the fundamental assumption underlying the assessment of personality traits have a long and extensive history in the professional literature. Hartshorne and May (1928) reported a program of research which found a high degree of specificity for honesty in children. Mann (1959) reviewed the literature on the relationships between personality traits and behavior in groups, covering studies reported in the period from 1900 to 1957, and found little or no association between these two classes of variables.

It is certainly striking to find that this area of psychology, which has a long theoretical and empirical history and which has provided the bases for an extensive applied technology, cannot answer a challenge to demonstrate the validity of the trait approach. Highest priority should be given to remedy this deficiency.

Establishing the validity of the trait approach will require an extensive amount of research and development. The assessment of personality traits is not a unitary undertaking; techniques of assessment vary on several dimensions, which include: (a) self-description data versus the judgments of others, (b) structured or unstructured test stimuli, (c) structured or unstructured response options to the test stimuli, (d) objective or subjective methods for scoring the responses, and, of course, (e) the topic of the trait itself.

Some evidence which gives support to the validity of the trait approach has already been reported. Winder and Wiggins (1964) demonstrated that individual differences in the social reputation which boys had among their peers for aggressiveness and for dependency were related to objectively recorded differences in the overt behavior of these boys in situations where aggressive and dependent behavior had a high likelihood of occurring. Gormly, Gormly, and Johnson (1972), dealing explicitly with the paucity of data supporting the validity of

² Mischel's position on personality assessment is far more extensive than a criticism of the trait approach; he presents a rationale for an alternative strategy to personality assessment (see Mischel, 1973).

stable individual differences, examined the consistency of four sociobehavioral responses which people use following disagreement with another. The four responses (conformity, underrecall of the extent of disagreement, interpersonal rejection of the disagreeing person, and devaluation of the significance of the disagreement episode) were studied for individuals who each participated in three sessions which differed in the kinds of disagreement topics and the extent of disagreement. The authors found a substantial amount of consistency in the extent to which subjects used these four responses in the three disagreement situations. Ross (1966) reported convergence between teacher ratings of dependency in nursery school children and objective indicators of dependency in the behavior of the children. These three studies indicate that some traits measured in certain ways have demonstrated an acceptable level of validity; additional examples of trait validity from the professional literature, however, are not extensive.

The following study was designed to extend information of the validity of personality traits by using peer ratings of aggressiveness for male college students. Pairs were formed in which one member was high on aggressiveness and the other person was low on aggressiveness according to peer ratings. In each session a pair was observed through a one-way mirror by groups of nonprofessional judges who made ratings at three points during the session regarding which member of the pair was more aggressive. Judgments were made (a) when the pair entered the room and seated themselves at a table without speaking, (b) when the pair had spent approximately 10 minutes discussing attitude topics on which they had opposite opinions, and (c) after the pair had played a game for cash rewards. The purpose of the study was to examine the degree of convergence of aggressiveness scores between ratings by peers who shared a home environment with the subjects and ratings by judges who saw the subjects behave for a brief period of time in the laboratory.

Method

SUBJECTS

The subjects were 16 male undergraduates from an eastern state university. Eight men came from one fraternity, and 8 men came from another fraternity. Both fraternities are participating in a longitudinal study (an investigation of the biological correlates of personality traits). Judges were volunteers from an undergraduate course in the psychology of personality.

PROCEDURE

Members of the fraternities rated themselves and other members of their fraternity for aggressiveness. The format for rating peers involved a binary decision. Raters were given a list of names of the members of their fraternity who were participating in the longitudinal study. They were instructed to put a 1 next to the person's name if they considered the description "aggressive-assertive with other people" to be characteristic of the person and to put a 0 next to the person's name if they did not consider the descriptive statement to be characteristic of the person. A person's score for aggressiveness was the proportion of raters who said that the trait was descriptive of him. There were 26 raters and 30 people being rated from Fraternity A, and there were 26 raters and 31 people being rated from Fraternity B. On the basis of these ratings, the 4 persons who had the highest scores for aggressiveness and the 4 persons who had the lowest scores for aggressiveness from each fraternity were asked to participate as paid research subjects in the present study; thus, we had 8 high-aggressive people and 8 low-aggressive people according to peer ratings.

In addition to peer ratings, each person rated himself on a 5-point scale of aggressiveness in the following format:

Aggressive-assertive with other people

____ I am more aggressive than most people.

____ I am more aggressive than average.

____ I am as aggressive as many other people—average.

____ I am less aggressive than average.

____ I am less aggressive than most people.

Each person was given a partner for the meeting that was to be observed by the judges. All pairings consisted of one high-aggressive person and one low-aggressive person. In one half of the cases a person was matched with someone from his own fraternity, and in the other half of the cases a person was matched with someone from the other fraternity.

The subjects agreed to participate in the study knowing only that they would be observed through a one-way mirror by undergraduates who would make judgments about their social characteristics. They did not know that they had been selected on the basis of peer ratings of aggressiveness nor that they had been assigned a partner who was in contrast with them on some trait.

CONDITIONS FOR MAKING JUDGMENTS

The judges were seated in two rows in front of a large one-way mirror which gave them good vision into the experimental room. The high- and low-aggressive subjects entered the experimental room accompanied by the experimenter who asked them to sit at a table in chairs which would have them facing each other. At this point the judges could not hear anything from the experimental room. When the subjects were seated, the judges were asked to indicate which person was more aggressive-assertive with other people, the person on their left or the person on their right (Judgment 1). The judges were asked to indicate what it was about the persons which made them decide as they did.

When Judgment 1 was completed, the experimenter initiated an audio system which simultaneously let the judges hear the subjects and the experimenter and tape-recorded the session.

Previous to attending this session the subjects had completed a large survey of social attitudes. The experimenter selected a topic for which the two subjects held opposite

opinions and asked them to try to convince each other of the merits of their own position. The experimenter let them discuss the topic for approximately 10 minutes. If they resolved their differences or exhausted their presentation of the issues before the 10 minutes were over, the experimenter would give them another topic. The experimenter placed no constraints on how the subjects were to behave during the discussion period.

When the experimenter terminated the attitude-discussion period, the judges made their second judgment. Again, they were asked to indicate which person was more aggressive-assertive with other people and to explain why they picked the person they did (Judgment 2).

When Judgment 2 was completed, the experimenter read the following instructions to the subjects:

I am going to show you words on cards. I would like you to respond to the word by using it in a sentence, but only one of you may respond to each word. It is up to you which of you uses each word, but there is a certain pattern of order in which you are supposed to respond. The only way you can determine the correct responding pattern is by trial and error. When one of you responds, I will tell you whether it was the right person or not. Each time I say "Wrong," that pattern starts over again. If you can make six correct responses in a row between the two of you within 10 words, each of you will receive \$2 for that pattern. We are going to do four patterns, so the most you can get for participating in this experiment is \$8. However, if you cannot correctly solve any of the patterns, you will still get the \$5 promised you for participation. You may, if you wish, discuss whatever you feel is necessary. The pattern has nothing to do with the actual word I show you. Are there any questions?

After reading the instructions, the experimenter informally explained the instructions. When the fourth game was completed, the judges were asked for their final judgment of which person was more aggressive (Judgment 3) and why they selected the particular person that they did.

The total amount of time that each pair was observed by the judges was less than 25 minutes. Each group of judges observed and rated two sessions; therefore, there were four groups of judges for the eight pairs of subjects.

One week following the initial sessions, the judges returned to listen to tape recordings of two attitude-discussion sessions. The judges had not observed the particular discussions which they heard at this session. After they listened to each pair discuss their differing opinions on attitude topics, the judges rated which person was more aggressive. The subjects were identified by their position on the topics.

The total number of judges at the initial sessions was 50. The total number of judges who listened to the tapes was 36.

Results

Analyses of the data were conducted to examine psychometric properties of the aggression scores. The peer ratings of aggressiveness for each person were divided into two groups to examine the split-half convergence of trait attribution for two groups of raters within the fraternities. Each person had two aggression scores; each score was based on the proportion of 13 raters who said the trait was char-

acteristic of the person. The split-half correlation coefficient was .81 for a sample of 61 men.

The total proportion of peers who attributed aggressiveness to a person was correlated with the person's self-description of his own aggressiveness. There was only a moderated degree of convergence for these two scores of aggressiveness ($r = .40$, $N = 52$).

Chi-square tests for association were conducted on the peer ratings and the data from the judges. The data were represented in 2×2 contingency tables: peer ratings of the subjects (high aggressive and low aggressive) and judges' ratings of the subject (high aggressive and low aggressive). The first judgments, which were based on physical characteristics and nonverbal mannerisms of the subjects, were significantly related to peer ratings ($\chi^2 = 9.2$, $df = 1$, $p < .01$). This represented a 65% agreement between the two groups of judges. The second judgment, which followed the completion of the discussion of attitudes, had a larger chi-square value than Judgment 1 ($\chi^2 = 16.0$, $df = 1$, $p < .001$). The third judgment, which followed the completion of the game, had the highest degree of concordance (72%) between peer ratings and judgments from observers in the laboratory ($\chi^2 = 19.4$, $df = 1$, $p < .001$). The contingency table for Judgment 3 is given in Table 1.

Judgments which were based on tape recordings of the attitude-discussion sessions were not significantly associated with peer ratings ($\chi^2 = 2.0$, $df = 1$, $p > .10$). The final test for association examined the number of correct and incorrect judgments (agreements with peer ratings) as a function of whether the members of the pairs came from the same fraternity or from different fraternities. Whether the pairs were constituted of persons who came from the same fraternity or different fraternities had no significant association with agreements or disagreements between judges and peer ratings ($\chi^2 = 1.8$, $df = 1$, $p > .10$).

TABLE 1

Relationship between Peer Ratings of Aggressiveness and Judges' Ratings of Aggressiveness

Judges' ratings	Peer ratings	
	High	Low
High	36	14
Low	14	36

Discussion

The results of this study provide strong evidence for the position that social aggressiveness can accurately be considered as a personality trait; that is, peer ratings of aggressiveness describe a recognizable component of a person's behavior which is consistent across situations. This conclusion is based on the high degree of agreement found in the split-half reliability of peers and the ratings of judges who observed the subjects in a laboratory setting.

The choice of social aggressiveness as the trait to be investigated in this study was influenced by several considerations, notably the wide variance and social importance which aggressiveness (or dominance) has for so many animal species and pilot work on a fraternity, which was not one of the fraternities included in the present study, in which the split-half reliability of peer ratings was .92 for a sample which had 31 cases. Therefore, it may seem that we "stacked the deck" in an attempt to support the trait approach. We are not inclined, however, to represent the findings of this study as a demonstration of the general validity of the trait approach. The validity of each trait measured with any particular method will have to be determined empirically. The findings of this study do present hard data which challenge general assertions claiming that the trait viewpoint has no substance whatsoever in describing some real facet of human behavior.

With the validity of peer ratings of aggressiveness clearly established, we can begin on four related undertakings: finding a more economical way of assigning a person an aggressiveness score which approximates peer ratings; detailing the observable, behavioral cues which influence the attribution of aggressiveness to people; developing the predictive utility of aggressiveness scores; and establishing the validity of other personality traits.

The task of finding an economical substitute for peer ratings is likely to be a difficult one. The data from the present study demonstrate that a person's self-description of his degree of aggressiveness is not a substitute for peer ratings. There are many sources of unwanted variance that enter into trait scores from self-descriptions. For example, the meaning of the words with which you are required to describe yourself probably vary from person to person, and the value (desirability) which people place on traits is probably quite idiosyncra-

tic. Sources of variance which enter into test scores have been well discussed elsewhere in the literature on personality assessment (see Wiggins, 1968).

While sources of unwanted variance which enters into self-descriptions probably have parallel forms in peer ratings, using large samples of peer raters may result in the unwanted variance being randomly distributed in the ratings and, consequently, having a negligible influence on each person's trait score. One immediate task is to find the minimum number of raters that can be used to approximate a larger sample of peer raters.

Although this study has provided evidence that peer ratings of aggressiveness describe a traitlike component of behavior, we do not know what observable cues influence ratings of aggressiveness. Obviously, it is not the content of what a person says when he argues his position on social attitude topics with a disagreeing other. When the judges listened to tape recordings of the high-aggressive and low-aggressive pairs, their judgments of who was more aggressive did not converge with peer ratings. The explanations of the raters on why they selected a person as the more aggressive are only moderately helpful at this point because many people respond with abstractions of behavior rather than with observable events. Frequently, the responders would say that they selected a person because he seemed more sure of himself, more confident, or more assertive. Among the observable cues most frequently given for naming one person more aggressive than the other were direct eye contact, banging on the table to make a point, directing who should respond during the game situation, and overtly showing dissatisfaction when the response during the game was said to be incorrect by the experimenter. When we know more about the behavioral characteristics which constitute a trait, then we will be a long way toward specifying under what conditions we can expect good predictive utility from a trait.

The format of the present study provides a model through which the validity of other traits might be demonstrated. In contrast to the "stacked the deck" evaluation of the method of this study, it is encouraging that the trait of social aggressiveness had such penetrance that the judges were able to be so accurate after less than 25 minutes of static observation. Consideration of the weak format under which the judges were asked to make their decisions strengthens the claim that the findings

of this study demonstrate validity for a personality trait and confronts radical challenges that the trait approach has no validity.

Contributions to Education in Psychology Awards

The American Psychological Foundation invites nominations for the 1974 Contributions to Education in Psychology award. The annual award is in the amount of \$1,000 to be given to the recipient for his achievements. It is hoped that the awardee's institution will contribute a matching sum, thus providing the recipient with a modest "grant" to be used by him as he wishes to "improve the teaching of psychology." Thus, the objective of the award program is to enhance the local instructional program, not just to recognize "master teachers." Because the awards are to be presented at the APA Annual Convention in September 1974, *nominations must be completed and sent to the Committee by March 31, 1974*. A nomination form with a statement of the guidelines and suggestions for documentation can be obtained by writing to Wilse B. Webb, Chairman, APF Teaching Awards Committee, Department of Psychology, University of Florida, Gainesville, Florida 32601.

Achievement Motivation in College Women

A Now-You-See-It-Now-You-Don't Phenomenon

THELMA G. ALPER Wellesley College¹

Beginning with the earliest studies by McClelland, Atkinson, Clark, and Lowell (1953), achievement motivation research based on male subjects typically has yielded significant and readily replicable findings. Until recently, however, this has not been the case when female subjects were used. An example of this discrepancy is that for males, achievement-oriented instructions (emphasis on leadership capacity and intelligence) increase the McClelland et al. (1953) need for achievement score, while task-oriented, neutral, or relaxed instructions depress it. Comparable shifts have rarely been reported for females. Instead, both achievement and neutral instructional sets evoke equally high need for achievement scores in women (e.g., see Alper & Greenberger, 1967; Veroff, Wilcox, & Atkinson, 1953). Similar discrepancies arise when other hypotheses are tested: Veroff, Feld, and Crockett (1966), for example, hypothesized that picture cues closely related to the storyteller's own occupation would be less effective evokers of achievement imagery than unrelated cues. This hypothesis held for male subjects, but not for female subjects. To cite one more example, in the French and Lesser (1964) study, despite some positive support for the major hypothesis, the thrust of their main argument concerning achievement motivation in women was weakened in the end by a wholly unanticipated, statistically significant, *contrary* finding.

In addition to the inconsistency of the findings across sexes, what is also striking is the relative paucity of studies based on females. A survey of the specialized texts in this area reveals just how minimal the research on women has been. The first

such text, *The Achievement Motive* (McClelland et al., 1953), devoted 8 of its nearly 400 pages to studies of women. By 1958, interest in the achievement and related motives had grown so rapidly that the record book *Motives in Fantasy, Action and Society* (Atkinson, 1958) required 873 pages to cover the literature, but the research on female achievement motivation was relegated to a single footnote (p. 77). Nine years later, Heckhausen (1967) in *The Anatomy of Achievement Motivation*, concentrating on the more recent American and foreign literature in this field, added only a handful of new studies based on female subjects. Of the 215 pages in this book, 9 dealt with sex differences.

Clearly, between 1953 and 1967, researchers seem to have been considerably less interested in female than in male achievement motivation. Why should this have been the case? Do equivocal and/or contradictory findings discourage continued research? Perhaps so. But a more fundamental question is, Why sex differences in the first place? Up to this point, most researchers seem to have assumed that male and female achievement motivation is governed by essentially the *same* laws, despite the theoretical implications of Field's (1951) early findings.

According to Field, achievement motivation in women, but not in men, is linked to the need for social acceptability, that is, the need to be liked. Prior manipulation of this need, it developed, could raise the McClelland et al. (1953) need for achievement score of women but had no effect on the scores of men. McClelland et al. (1953) interpreted these findings to mean that for women the achievement motive is less central than the affiliative motive, while the reverse is true for men. If this is so, it follows that if one wishes to study achievement motivation in its pure form, one *should* use male subjects, and as Sarason and Smith (1971) decried, this is exactly what most researchers have

¹ This article was presented originally as the presidential address at the meeting of the New England Psychological Association, New Haven, Connecticut, November 1971. It has been updated to include additional studies.

continued to do. But why, then, was Field's affiliation lead not more fully pursued? Unfortunately, affiliation arousal, at least within Field's framework, also turned out to be undependable for arousing need for achievement in women (see Atkinson's [1958] report of Vogel's [1954] findings).

Throughout the 1950s and 1960s a few investigators continued to use the original McClelland et al. (1953) approach for arousing achievement motivation, encouraged, perhaps, by Angelini's (1955) findings that an achievement-oriented instructional set could significantly increase the achievement motivation scores of women as well as of men. Though Angelini's results turned out to be no more readily replicable than those of Field, a number of seemingly relevant variables did begin to emerge. Among these were sex of the stimulus figures (Alper, 1957; Lesser, Krawitz, & Packard, 1963; Veroff, Wilcox, & Atkinson, 1953), the effect of the sex and position of the stimulus figures relative to each other (Alper & Greenberger, 1967), differences in value orientation (French & Lesser, 1964; Lesser et al., 1963), and age and family situation of the storyteller (Baruch, 1967).

With the publication of Matina Horner's (1969, 1970) work, a more substantive answer to the question as to why the past research on women had not been more fruitful came into prominence: Women, according to Horner, do not really want to be achievers, they want to be liked. Field's (1951) data had, of course, already pointed in this direction. But now the evidence was more compelling. Given the stimulus "After first term finals, Anne finds herself at the top of her medical school class," over 65% of Horner's University of Michigan coeds told avoidance of success stories, while to the "John" form of the stimulus, over 90% of the male subjects told success stories. Both the intrasex and intersex differences were statistically significant. Because the avoidance themes in the Anne stories focused mainly on Anne's fear (a) that no one would like her now that she was so achieving, or (b) that because she was so achieving perhaps she was not really very feminine, Horner's findings would seem to indicate that even in these days of women's liberation, on the projective level at least, women still perceive female achievement to be incompatible with the values of our culture. How else can one explain the vehement denial of Anne's achievement? We are told "the computer made a mistake"; or "it was just a fluke"; or "she won't be able to keep it up."

The 65% avoidance reported by Horner in 1968, 1969, and 1970 was based on the sample of 88 females she tested in 1964. Would more recent testing yield as high a percentage of avoidance stories? Using the same stimulus with a sample of "very high ability juniors at an outstanding coed university where the emphasis on achievement is very high," Horner (1972, p. 64) reported that 85% of these later subjects told avoidance stories! Our own data, based on Wellesley College undergraduates tested in the academic year 1970-1971, are of this same order. Given the Anne stimulus, almost 89% told avoidance stories. The sample here, though limited to 26 students, can be regarded as reasonably representative of the college population.

To get a measure of how females would react to the John form of the stimulus, we used a second group of comparable size. Now the percentage of avoidance stories plummeted to 50, a significant shift from the 89% told to the Anne stimulus, though still higher than the less than 10% Horner (1968) originally reported for her male subjects. In other words, not only do these very bright women seemingly not want (expect) to be achievers themselves, but they may also expect (want) men to be less achievement motivated than men really are. Data obtained on a comparable sample of 40 Dartmouth College males in response to the Anne stimulus did not support a similar pattern in men's expectations of women. Quite to the contrary, only 62.5% of the men told avoidance stories,² as compared with the 89% noted above in the Wellesley College data. This difference is statistically significant. Can it be that the nontraditional concept of the achieving woman is now more acceptable to men than to women? Two stories taken from the Dartmouth College sample convey the flavor of many of the protocols: The male storyteller recognizes Anne's fear of success and tries to allay her anxiety.

Anne: "Christ! I don't believe it."

John: "Anne, that's great. I mean it's fantastic!"

Anne: "I don't know John, I mean, I never expected anything like this. I mean, God, I'm going to have to think about this."

John: "What's to think about, you made it, you're on top!"

* * * * *

Anne did all the work assigned to her during the term and

² N. Marcuse & E. McMonagle. Achievement Motivation in College Males. Unpublished paper, 1971. In preparation.

occasionally extra but she certainly did not expect to be at the top of her class at the end of finals. When she realized this she was very pleased but subconsciously worried about the reactions her fellow students would have. Would they think her above them and avoid her? This bothered her to such an extent that she tried to keep it to herself but one day soon after a good friend approached her and said, "Congratulations, Anne, I hear you're at the top of your class. I'm really proud of you." And Anne was too.

Lois W. Hoffman's (personal communication, February 1973) recent replication of Horner's (1968) original design suggests that the traditional concept of the achieving man may also be becoming less acceptable to men. Tested in the early 1970s, 79% of Hoffman's University of Michigan male subjects told avoidance of success stories to the John stimulus. This is a striking change from the less than 10% avoidance Horner obtained approximately eight years earlier. Hoffman's female subjects, however, did not show a comparable shift over time. Instead, avoidance of success continued to be the major female response to the Anne stimulus.

But can we really conclude from the studies to date that American women do not want to be achievers? Variations in the percentages of avoidance stories from study to study are fairly large, suggesting that sampling differences, as well as the wide range in years of testing, may be affecting the results. In addition, Anne's achievement is in a traditionally female-inappropriate field, that is, medicine. Is this what makes Anne's success so dangerous? To answer this question, in one set of studies we dropped the medical school reference leaving only "After first term finals, Anne finds herself at the top of her class." As predicted, in repeated samplings at Wellesley College, the reworded stimulus evoked significantly fewer avoidance stories than the original wording; the percentage typically approached 50. Similar results have been obtained with female subjects tested in other noncoeducational settings. For example, in a study done in two southern colleges, one for black women, the other for white women, the new wording evoked 36% avoidance of success stories for the black sample and exactly 50% for the white sample.^a

If the cultural stereotype has been the real villain here, then changing the stimulus to read "After first term finals, Anne [John] finds herself

[himself] at the top of her [his] nursing school class" should result in a significant *increase* in the percentage of success stories in female subjects and a significant decrease of such stories in male subjects. To date we have tested only the first half of this proposition. In this study, the subjects were enrolled in two different noncoeducational colleges. One group consisted of 30 junior college women, all of whom were preparing to be nurses; the other of 37 women in a small, four-year liberal arts college. Within each group, half were given the "Anne medical school" stimulus, and half the "Anne nursing school" stimulus. The hypothesis was upheld only for the first group, those who were preparing to be nurses. For these subjects, the medical school form evoked 20% success stories; the nursing school form, 86% success stories. This difference was statistically significant ($\chi^2 = 7.23$, $p < .01$). In the liberal arts sample, however, the two forms evoked success and avoidance stories about equally often. The striking finding with this latter group was the valuing of a liberal arts education and the devaluing of nursing as a career for women. Whether the "nursing school" stimulus would yield similar results in a sample drawn from a more prestigious four-year liberal arts college remains to be seen. Similarly, should we expect professionally oriented but not nursing-oriented females to respond as the nurses do, that is, with success stories?

In short, the now-you-see-it-now-you-don't phenomenon in female achievement motivation research may be attributable to wide differences in how the motive has been measured. Yet, if we are to account for the sizable group of coeds who *do* tell success stories (35% in Horner's original sample; 50% at Wellesley College when the medical school reference was omitted), the search must go beyond sampling and stimulus variables.

As early as the 1950s, evidence was beginning to accumulate which demonstrated that personality factors could affect the achievement motivation scores of women. Field, it will be remembered, had proposed as early as 1951 that being liked was more important to women than to men. Morrison's (1954) finding that the need for achievement scores of females elected by their peers to positions of leadership were significantly higher than those of nonoffice holders is consistent with Field's proposal, if one assumes, as Morrison did, that females who seek office *are* more concerned with peer acceptance (i.e., popularity with peers) than females who do not. Three years later, Alper (1957) reported similar results, but only when the stimulus figure was

^aB. Grainger, B. Kostick, & Y. Staley. A Study of Achievement Motivation of Females in Two Southern, Noncoeducational Segregated Colleges. Unpublished paper, 1970. In preparation.

male. Yet, the connection between concern for peer acceptability and associating achievement as more appropriate for males than for females had not yet become explicit.

The first step in this direction was taken by Lesser et al. (1963) when an unexpected, statistically significant interaction emerged in their data: Bright, high-achieving high school girls scored higher on need for achievement only when responding to *female* picture stimuli under an achievement-oriented, as compared to a more neutral, instructional set, while equally bright underachievers showed the increase only to the *male* pictures. The authors had anticipated that both groups would show the increase to both sets of pictures. Using Mead's (1949) sex role stereotype argument, Lesser et al. (1963) argued that unlike the underachievers, the high achievers *do not* accept the cultural stereotype that achievement is female inappropriate. A follow-up study by French and Lesser (1964) supported this interpretation only in part. Using a specially designed role-orientation value measure, they found that woman's-role-oriented college women did indeed score higher on need for achievement, as measured by French's Insight Test, when responding to statements about women engaged in domestic and social activities, while intellectually oriented college women scored higher when the activities involved intellectual pursuits. But clearly this was not the whole story because, regardless of individual role orientation, achievement scores were always higher under the intellectual set when the stimulus involved males. Apparently, the values of the culture can transcend personal values. The extent to which the particular format of the value-orientation measure (as used in this study, "answer as you think *most girls* would answer") may favor this type of transcendence is worth considering. This should not, however, negate the seeming importance of the role-orientation variable. And this is where our work at Wellesley College began.

Our basic hypothesis has been that traditionally role oriented women, as in Mead's (1949) framework, are less likely to be achievement oriented (e.g., career oriented) than women whose role orientation is nontraditional. In testing this hypothesis, three considerations have dominated our research: (a) the need for, and construction of, a viable role-orientation measure; (b) the selection of stimulus cues for evoking achievement motivation; and (c) the development of methods for scoring the resulting protocols. Since the rationale of the procedures we used for meeting each of these objec-

tives is described elsewhere (Alper, 1973), only a brief report is included here.

After trying out a number of standardized femininity-masculinity scales, we finally decided to design our own. The end product, known now as the Wellesley Role-Orientation Scale (WROS), is a 24-item pencil-and-paper self-rating scale consisting of three 7-item subscales and three filler items. The three areas tapped by the subscales are (a) traits college girls generally regard as "feminine" rather than as "masculine"; (b) role activities they find acceptable for themselves as women; and (c) career and/or career-oriented activities they consider more appropriate for men than for women.

In our current work, the WROS has imbedded in it the 38-item Levinson and Huffman (1955) Traditional Family Ideology Scale (TFI). Presented as a "questionnaire designed to sample opinions and attitudes toward problems facing college girls," the subject was originally required to indicate merely agreement or disagreement with each item. We are now using a 7-point scale (from strongly disagree to strongly agree). Unlike French and Lesser (1964), we ask the subject to answer in terms of how she herself feels about each statement. In repeated samplings, the correlations between the TFI and the WROS continue to be positive and highly significant (i.e., high-WROS scorers favor a traditionally oriented family pattern; low-WROS scorers do not). On the other hand, the WROS seems to correlate only weakly with the sex-stereotype measure of Rosenkrantz, Vogel, Bee, Broverman, and Broverman (1968) and not at all with the Crowne-Marlowe (1964) Social Desirability Scale.

The first extensive use of the WROS with Wellesley College undergraduates was begun in the academic year 1964-1965. At that time, the typical range of scores for unselected samples, using the agree-disagree format, was 5-19, the total possible range being 0-21. Through 1967, the average score remained at 8.5. By 1969, the typical range was more constricted, 4-14, and the average had dropped to just under 8. In current samplings at Wellesley College and other comparable noncoeducational eastern schools, 14 remains the top score for unselected samples, but at the lower end there is an occasional 2 and an even more occasional 1.⁴

⁴B. Grainger. The Motive to Avoid Success and Its Relationship to Sex-Role Orientation in College Women. Unpublished honors thesis, Wellesley College, 1971. In preparation.

The average now approaches 7 rather than 8. As expected, moreover, the range for a small "consciousness-raising" group, a highly selected Wellesley College sample, is very constricted, 1-8. Yet even for constricted samples, the scores continue to have validity. Dividing the distributions into thirds, highs and lows within these constricted distributions differ from each other in the same ways as do highs and lows from wider distributions. What are these differences, and how have we tested for them?

Having suspected that the now-you-see-it-now-you-don't aspect of previous findings in this area might in part be attributable to differences in the strength of the achievement cues, we chose for our initial study the two pictures which Veroff, Atkinson, Feld, and Gurin (1960) had found particularly effective for arousing achievement imagery in adult subjects, namely, their "chem lab" and "machine shop" pictures. The chem lab shows two women in a laboratory setting; in the machine shop the two figures are men. In both, one person is watching, while the other is actively working at a task.

Using the McClelland et al. (1953) creative imagination instructions, but omitting all references to leadership capacity and intelligence, we found that both pictures did indeed pull strong achievement imagery as measured by their discrete variable scoring approach. But the need for achievement scores so derived did not differentiate between subjects who scored at different points along the WROS continuum, nor did the total score distinguish between successful and unsuccessful achievement striving. A more clinically oriented scoring scheme was needed. Since even a cursory review of the stories revealed a number of different themes, we decided to try a theme analysis. We subsequently learned that Horner (1968) had also abandoned the McClelland et al. (1953) scoring system in favor of a theme analysis and that only then did the striking sex differences in her data emerge.

For reasons detailed elsewhere (Alper, 1973), blind theme analysis works well for the chem lab stimulus and less well for the machine shop. For the chem lab, four major theme categories emerge: *successful achievement*; *dangers of achieving*; *task completion* devoid of achievement striving; and *themes unrelated* either to achievement or task completion. Within Horner's framework, the four would reduce to two categories: *success* and *avoidance of success*.

With rare exceptions, theme category and role

orientation, as measured by the WROS, have been found to be clearly related: Success stories are significantly more often told by low-WROS scorers (subjects who score in the lower third of the WROS distribution) than by high-WROS scorers (subjects who score in the upper third). In Wellesley College parlance, the first group is referred to as the "low fems," or "lows," the second group as the "high fems," or "highs." Some highs also tell success stories, but as is shown below, their stories differ markedly from lows' success stories. "Danger" stories appear at both ends of the WROS continuum with about equal frequency, while task completion and unrelated themes are more typical of highs than of lows.

Lows' success stories include four subthemes: hard work pays off; support by an achieving model; achievement through cooperative effort; and achievement facilitated by competition or rivalry. Here is an example of the hard work pays off subtheme, as told by a low:

This lady scientist, like Madame Curie, is about to make an amazing discovery. She has been trying for months to find a cure for cancer and in spite of almost giving up because of repeated failures, she and her assistant know that this is the moment. If she drops the right amount of solution into the tube, it will neutralize and that will be the answer to her years of effort. She will do it.

The next story, also told by a low, illustrates the support subtheme:

The instructor is showing her student how to do a step in a complicated experimental procedure. The student has been working on the experiment for some time, and is nearly at the end of her work. She is observing carefully what the other woman does, and, when she returns to her own work, will repeat the procedure with care and precision and will be able to finish her project and achieve significant results. The instructor would like the student to become an able scientist, and is pleased with her work.

Highs' success stories are characterized by very different subthemes. These include instrumental success (the achievement is instrumental to the gratification of a need other than achievement qua achievement, usually affiliation); woman as man's helper; and to achieve, women have to work harder than men. An example of each, as told by highs, follows:

[Instrumental success] Two unmarried Wellesley College chemistry professors are titrating a solution. They expect to find a new theory of nuclear activity involved in the solution process that will be critical to the instant coffee concerns. They hope to make a lot of money so they can go on a cruise and meet some eligible bachelors. They both fall in love with MIT professors and live satisfiedly ever after.

[Woman as man's helper] These two ladies are PhD holders in chemistry who are working for the hospital in a surgeon's research laboratory. They are married but wanted to do something for a career with research work filling the bill. They don't want fame but rather to help mankind in their small way to find a cure for hepatitis. They will be of great assistance to the doctor and will perform a valuable function in doing the tasks that the doctor doesn't have time to do.

Note that the first story is present oriented (finding husbands), while the second appears to be future oriented (after marriage). Stories in this latter category often explicitly state that the women no longer have young children to tend to.

The next story illustrates a high's version of the hard work pays off theme, with the special twist that to succeed, a woman would have to work *harder* than a man:

It is a time when women scientists are not common. They are in the minority and are often looked down upon by men. Therefore, they have to work extra hard to prove themselves. These two female technologists are working on a biochemistry experiment. The one standing is trying to train the younger woman whom she feels has much potential. Through their hard work and dedication to their project they will succeed. They will not only make a name for themselves . . .

Since the *project* is successful, the protocol qualifies as successful achievement. But whether the achievement finally wins them acceptance by men is less certain. The story remains unfinished. Moreover, a downgrading of the status of the women (here to technologists) occurs to this stimulus only in the stories told by highs.

Combining the dangers of success, task completion, and unrelated imagery themes into a single category, avoidance of success, it is clear that it is the highs, not the lows, who tell such stories.⁵ The difference between the two groups is statistically significant. As noted above, both highs and lows tell stories involving dangers of success. But there is a striking between-group difference in the nature of the projected danger: For highs, the danger is either to the *person* of the achiever or to her interpersonal relationships; for lows, the danger is that the *project* will fail. Thus, it is the highs' avoidance pattern, rather than the lows', which is the better fit for Horner's (1968, 1969, 1970) category of avoidance of success as a way of coping with the fear of being disliked.

⁵ In the McClelland et al. (1953) scoring system, "danger" stories would qualify as achievement imagery (AI), whereas task completion stories and stories unrelated to achievement would be scored as TI and UI, respectively.

Here is an example of a danger of success story, as told by a high:

The lady with the test tube is a movie star who has sunk to doing TV commercials. The other is an admiring nobody [who] pities her . . . They both fade into oblivion. No one will like them or pay attention to them . . . The star commits suicide and the other marries a florist and gets fat.

The story, though perhaps tongue in cheek, seems to have a moral: A career, even a glamorous one, can only lead to "oblivion"; better to settle for the more conventional, if somewhat unshapely, role of the married woman.

The downgrading of the status of women in the chem lab situation turns out to be more characteristic of highs than of lows only when *both* stimulus figures are female. It does not hold when the stimulus involves a man and a woman.⁶ Using specially posed picture stimuli,⁷ we had expected that highs would perceive the male as having the higher status regardless of his role, worker or watcher, while lows would assign the figures equal status roles. But the chi-square analysis of the data failed to support this simplistic prediction. On the other hand, the overall results are consistent with the role theory framework of the research as a whole. Though both pictures now tend to evoke more success stories from highs than from lows ($.10 < p > .05$), unlike lows, highs typically attribute the success to the man: When the man is the worker, he achieves his goal, he solves the problem at hand; when the woman is the worker, the man instructs her, that is, tells her how to perform the task, and if the project is successful, it is the man who is credited with the achievement, the woman serving merely as his assistant. In lows' success stories, the success is the result either of the joint efforts of the two people or of the woman in the role of the worker. In other words, highs continue to perceive achievement as female inappropriate; lows do not.

But life for the achievement motivation researcher is never simple when the subjects are females. The results just reported were based on data obtained at Wellesley College in September

⁶ T. G. Alper, H. Leet, E. Bragg, & D. Z. Eister. The Effect of the Sex of the Stimulus-Cue Figures on the Achievement Fantasies of College Women. Unpublished paper, 1972. In preparation.

⁷ The seeming age differences between the two figures in the original chem lab picture, their relative positions and postures, as well as the laboratory equipment, were reproduced as closely as possible in the new stimuli.

1971 on the opening day of classes. The subjects were 24 upperclassmen, all members of a limited-enrollment upper level course entitled "The Psychological Implications of Being Female." Because students accepted in the course are required to meet several departmental prerequisites, the sample, though captive, could be regarded as a self-selected, special interest group. Would a less psychologically sophisticated sample of underclassmen respond in the same way? To answer this question, we tested the 113 women in our beginning psychology course, dividing them at random into two groups. The woman-watching-man-working picture was shown to one group; the man-watching-woman-working picture, to the other. Differences in the WROS scores of the two groups were well within the limits of chance.

A chi-square analysis of the data failed to confirm the findings for the older group because now both pictures tended to evoke more avoidance of success than success themes. In the group given the woman-watching stimulus, 80% of the lows and 82% of the highs told avoidance stories ($p < .01$ within each group). To the man-watching stimulus, 69% of the lows and 80% of the highs told avoidance stories. The difference for lows was not significant but that for highs approached significance ($.10 < p > .05$). Incidentally, both pictures evoked significantly more avoidance than success themes in middle-WROS scorers.

On the surface, then, the data for these younger, less psychologically sophisticated college women are seemingly more consistent with Horner's (1968) basic Anne stimulus findings than with either our original chem lab data or the new data for the older group. It is only when the individual WROS scores for all 113 subjects (highs, middles, and lows) are subjected to an analysis of variance for unequal N s that role orientation again emerges as an important variable. Picture cue, thema, and perceived status of the man and woman, as separate factors, turn out not to be related to WROS scores. Status \times Picture Cue is related, however: Regardless of thema (success or avoidance), the mean WROS score of subjects who tell unequal status stories is lower for the man-watching picture; for the woman-watching picture the mean WROS score is lower for subjects who tell equal status stories ($p = .05$). It is the woman-watching situation, then, which, regardless of the fate of the project, more readily permits the egalitarianism of lows to emerge.

From the beginning of our research with the

role-orientation variable, we suspected that neither the highs nor the lows necessarily represent dynamically homogeneous groupings. Returning to our original data using, for example, the Veroff et al. (1960) chem lab stimulus, though most highs told avoidance of success stories, a few told instrumental success stories. Within the lows, most told straightforward success stories; a few expected the project to fail. The differences in these themes call to mind four of the patterns that Douvan and Adelson (1966) described as characteristic of adolescent girls: the unambivalent high feminine, the ambivalent high feminine, the unambivalent low feminine, and the ambivalent low feminine. Douvan and Adelson are of the opinion that both ambivalent groups are in conflict about their femininity even though they admit that they have no direct evidence to support this. Our projective approach would seem to offer a viable vehicle for accumulating relevant evidence. What seems to be needed here, however, are stimuli which, unlike the laboratory setting of the chem lab, readily lend themselves to opting for alternative roles: domestic, nondomestic, or some combination of the two. To this end, we used a new picture stimulus, the "kitchen scene."⁸ A youngish woman is seen in the foreground, and a small child, seated in a high chair, is to her right. The woman is painting the child's portrait. In the left background, something (a cake, pie, roast?) can be seen through the glass panel of the oven door.

The subjects for this study were 78 Wellesley College undergraduates, all members of the author's child psychology course. The testing was done during the first meeting of the class before any instructor bias could have influenced either the WROS scores or the thematic content of the stories. Thema differences between high- and low-WROS scorers were in the predicted direction and clearly significant (the chi-square, corrected for continuity, was significant beyond the .001 level).

The themes most frequently found in the highs' data were as follows: (a) Motherhood is put ahead of a career; the woman puts the painting aside in order to attend either to the baby's needs or to her own need just to enjoy or play with the child. (b) Motherhood and achievement are casually combined; painting is described as a hobby, and the end product is destined to be given either to

⁸ The author is indebted to the Boston Gas Company for permission to reproduce this picture from one of their advertisements.

dotting grandparents or to an equally appreciative husband. (c) Motherhood and a career *cannot* be combined. One may wish to combine them, but in the end, achievement wishes must be put aside for they get one into trouble—one cannot be both a professional and a mother. When one tries to combine roles, the cake burns, the child gets restless, or the husband disapproves—he wants his dinner ready when he gets home. Logically, *Themas a* and *b* would be appropriate to the high who is unambivalent in her acceptance of the role the culture traditionally assigns to women, while *Thema c* suggests some discomfiture with the demands of the traditional role, yet a need somehow to stay with it.

The *themas* most frequently found in the lows' data were as follows: (a) A career is placed ahead of the wife and mother role; the woman is a professional artist who has been called in to do the portrait. (b) Career, marriage, and motherhood can be successfully combined; the woman is an accomplished artist and is continuing to use her talents now that she is married. (c) Marriage and career cannot be combined; marriage is fraught with disappointments for one has to give up too much; therefore, it is better to walk out on the marriage and to pursue the career. All too frequently the career also fails, not because the woman is inadequate, but because society is. Again, logically, *Themas a* and *b* would be consistent with the value pattern of the unambivalent low, while *Thema c*, with its introduction of the danger theme, would be more characteristic of an ambivalent low.⁹

Having identified ambivalence-unambivalence by a fantasy measure, the next question is, Can these patterns be predicted from the WROS alone? While we do not yet have a definitive answer to this question, the two procedures we have worked out to test it seem promising. One procedure is based on decision-time theory; the expectation being that highs who are role ambivalent, as measured by *thema* category, will take longer to agree with the WROS items than highs who are role unambivalent, while lows who are role ambivalent will take longer to disagree with the items than lows who are role unambivalent (see Footnote 4). The other procedure uses the standard deviation of

the subject's WROS score. The expectation here is that a role-ambivalent subject, again as measured by *thema* category, will have a larger variance around her own scale mean than a role-unambivalent subject. The first procedure could be used with either of the WROS formats: agree-disagree or strongly disagree-strongly agree. The second procedure would be suitable only for the latter format, strongly agree-strongly disagree.

Our search for the antecedents of differing achievement motivation patterns has just begun and has included so far both projective approaches and life-history data. The life-history materials are still too incomplete to report, but we do have some new projective data derived from a large sample of Wellesley College undergraduates, mainly freshmen and sophomores. The stimuli used here were two parent-child pictures. One, a mother figure and little girl, is an altered form of Murray's (1943) Thematic Apperception Test Card 7GF. The other, a father figure and little girl, is Card 10G from the Michigan Picture Test (Andrew, Hartwell, Hutt, & Walton, 1953). In both pictures, the figures are facing each other.¹⁰ In addition to the modified creative imagination instructions described earlier, half of the subjects in this study were told that the grown-up in the picture was "upset about something," the other half that the "child was upset about something."

Our analysis of the data has centered around two questions: (a) Do highs and lows react differently to these two instructions? (b) Does sex of parent figure make a difference? We found that the *themas* for high- and low-WROS scorers *do* differ significantly; sex of parent makes some difference within each group, but the person who is upset, parent or child, does not. Regardless of sex of the parent figure, and regardless of which figure is said to be upset, highs significantly more often than lows attribute the upsettedness to the child's poor academic achievement ($p = .01$); in lows' stories, more often than in highs', the cause of the upsettedness is behavior unacceptable to the adult ($p = .01$). The most common complaints here are defiance of parental authority and clumsiness. Only occasionally do lows mention poor achievement. But when they do, lows see the parent figure under these circumstances as supportive and nurturant, while highs see the parent

⁹ The intensity of the anger expressed by many of these girls suggests Shils's (1954) pattern of "far left authoritarianism" rather than genuine egalitarianism. See Bardwick and Douvan (1972) and Rossi (1972) for further discussions of sex role ambivalence.

¹⁰ For a more detailed description of these stimuli, see Alper and Greenberger (1967).

figure as derogating and punitive. There is also a between-group difference in the outcome of such stories. In lows' stories, the child typically ends up as an achiever; in highs' stories, performance is typically not improved. While these differences occur in response to both pictures, they reach significance for the father-daughter picture ($p = .05$) and approach significance for the mother-daughter picture ($.10 < p > .05$).

The crucial question, of course, is, Are lows, in fact, better achievers than highs? There is some evidence that they are. For the subjects who served in the original WROS study (Alper, 1973), both weighted Scholastic Aptitude Test scores and college grades were available. The Scholastic Aptitude Test scores of highs and lows did not differ, but the college grades of the lows tended to be higher ($p = .10$). Lows, then, not only fantasize achievement, they actually do achieve. Judging from these data, it now seems likely that the high-achieving high school girls in the Lesser et al. (1963) study, the highly competitive, high-achieving coeds in Angelini's (1955) Brazilian study, and Horner's (1970) University of Michigan coeds who not only told success stories in response to the Anne stimulus but also performed better in competitive situations would all have at least one factor in common: Namely, they would presumably all score as lows on the WROS. Perhaps these girls also have in common a history of positive parental support and encouragement to be achievers, a pattern some investigators associate with high need for achievement in latency-aged boys (e.g., see Rosen & D'Andrade, 1959; Smith, 1969). As for our high-WROS scorers, if in fact they have been exposed to a more authoritarian child-rearing climate than our low scorers, as the high-positive correlation between the WROS and the TFI suggests, then the recurrent thema of the dangers of success which runs through their fantasy material, as well as the perception of parental figures as derogating and punitive, are also consistent. In such a climate, female achievement presumably would be regarded as sex inappropriate and would not be positively reinforced.

In conclusion, the now-you-see-it-now-you-don't phenomenon in the female achievement motivation literature appears to be a function more of wide methodological differences from study to study than of basic instability of the motive. Among the more important variables to be considered here are (a) personality factors, specifically differences in the sex role orientation of the subjects; (b) sampling

differences (e.g., age, psychological sophistication, degree of ego involvement in the task, and perhaps even intrinsic differences in the demand quality of the settings from which samples are drawn—the more social, affiliative, emphasis of coeducational institutions versus the more academically competitive emphasis of the noncoeducational); (c) form and contextual differences in stimulus cues ranging from unspecified area and level of achievement to very specifically sex-inappropriate areas; and (d) differences in the procedures used in scoring the resulting protocols. The effect of experimentally manipulating such factors has been demonstrated in the new research reported here and in references to studies by other investigators.

One other shortcoming of some of the previous work in this area should be mentioned: a too rigid adherence, especially in the early studies, to the male model of achievement motivation. In our culture, men are not only expected to achieve, they are also expected to want to achieve. Women, on the other hand, have neither been expected to achieve, nor to want to do so. It now appears that both generalizations may be too broad, that indeed a reversal of attitudes may be taking place, with men now less interested in being achievers (Hoffman, personal communication, February 1973), and women more willing to recognize that achievement may be female appropriate as well as male appropriate.

Learning Theory

Two Trials and Tribulations

P. E. FREEDMAN *University of Illinois, Chicago Circle*

MARK COHEN *University of Illinois, Chicago Circle*

JOHN HENNESSY *University of Illinois, Chicago Circle*¹

Certain things in life are sacred. Among them are cows, tenure, and some basic laws of learning. Since cows are difficult to bring into the laboratory and tenure keeps us in the laboratory, we are left with basic laws of learning to desecrate. One law which is most basic is the very simple statement of learning theory: When an organism makes a response and that response is followed by reinforcement, there is an increase in the probability that the response will be repeated under the same stimulus conditions. However, Spence (1956) called attention to the need for learning theory to stipulate the initial and boundary conditions under which its hypotheses will hold. In this context, Zimbardo (1969) emphasized that the traditional principles of motivational control must be supplemented with some cognitive postulates. And Orne (1962) stressed how the demand characteristics of the situation may affect response tendencies in experimental settings.

There is no more severe attack on any statement than to propose its opposite. Therefore, we offer, and propose to investigate, the following speculation: Initially, in the learning situation, when an organism makes a response and that response is followed by reinforcement, there is an increase in the probability that the response will *not* be repeated under the same stimulus conditions. This hypothesis is predicated on the rather basic assumption that an organism, prior to exposure to an experimental situation, has had many and varied experiences with reinforcements and has learned through these experiences that once reward has

been consumed or removed, it does not magically renew itself.

A fairly well documented example of such behavior comes from the animal spontaneous alternation literature (Freedman, 1965; Glanzer, 1953; Montgomery, 1951; Thompson, 1962). This is the tendency for an organism, when given two alternatives from which to choose, to select on the second opportunity the opposite alternative from that chosen on the first opportunity, even if the first was reinforced. It has been traditional to attribute such behavior to curiosity and/or exploration. An example of such behavior, dubbed but not explained as the *negative recency effect*, has been found in choice behavior in nine-year-olds and adults (Stevenson & Weir, 1961), but is curiosity the most explanatory mechanism?

This suggested one of the simplest mini-experiments that could be designed for human subjects. A box was constructed of wood 46 centimeters \times 46 centimeters \times 46 centimeters and painted black. (Psychologists have a propensity toward black boxes.) Two round holes with a diameter of 10 centimeters were cut on top and two lids, one with a square and one with a circle, covered the holes. Underneath each hole was a Pyrex cup 9 centimeters in diameter and 5 centimeters deep. A curtain could be drawn around the box to preclude a subject from viewing the top of the box and from observing manipulation with any of the cups.

The first group of subjects to be tested consisted of 32 traditional introductory psychology student compulsory volunteers. The procedures and instructions were as simple as the design. Prior to the subject's entry into the experimental room, each of the two cups was loaded with a quarter. The subject was brought into the room and given the following instructions: "I want you to choose one of these two lids. Lift the lid you choose, and,

¹ The experimenters would like to thank Robert Dulski for his assistance in data collection.

Requests for reprints should be sent to Philip E. Freedman, Department of Psychology, P. O. Box 4348, University of Illinois, Chicago, Illinois 60680.

if anything is in the cup beneath it, reach in and take it to keep. Go ahead." After the subject selected and pocketed the quarter, the lid fell closed and the subject's name, age, sex, and favorite activity were recorded as a time filler. For half of the subjects the curtain was drawn between trials, simulating a guessing game. For the other half no curtain was used. The instructions were then repeated, and the response was made and recorded. A verbal probe requesting why each response was made ended the experiment. If the subject chose the same alternative on the second trial, the response was recorded as a repetition. If the opposite response was made, it was recorded as an alternation.

In this first experiment, when the curtain was closed, the number of alternation responses was 5, and the number of repetition responses was 11. With the curtain open, there were 8 alternations and 8 repetitions. Typical responses to the verbal probe were, "No reason," "I like squares," and "Because." The score was Subjects 1, Experimenters 0. We were left in the position of accepting the fact that some subjects went back to cups they had just emptied and about as many did not, independent of conditions. We were also left with the impression that college sophomores are strange.

Meanwhile, another experimenter had taken the black box out into the real world to test children ages 3-11. Using the same basic instructions and nickels as rewards, the results were 11 out of 12 alternations with the curtain and 12 out of 13 alternations without the curtain. We gave ourselves $\frac{1}{2}$ point for obtaining alternation and gave the subjects $\frac{1}{2}$ point for not showing differential responses to the curtain. The score was Subjects 1.5, Experimenters .5.

Children alternate; adults go back to empty dishes! This is absurd. We reasoned that one basic source of repetition found in the college students could be an anticipation of deception. We therefore sought out what we hoped would be a less suspecting subject pool. We took our black box to the School of Nursing at the University of Illinois Medical School.

Without mentioning the word *psychology*, we solicited 25 volunteers, and got 3 out of 13 alternations with the curtain and 6 out of 12 alternations without the curtain. The score was Subjects 2.5, Experimenters .5. We were clearly losing.

Daunted, but not without the persistence characteristic of scientists who pursue rational hypotheses in spite of data, we decided on one last and

desperate venture. Having had more success in the real world (with children) than in the laboratory, we set out once again. (Our major thrust was to reduce any hint of deception to a minimum.) As experimenters, we used 14 undergraduate honor students from the introductory psychology course. They were naive with respect to our hypothesis (but they might have guessed). The black box with its attendant curtain and Pyrex cups was locked away in the storage closet, and each experimenter was equipped with two identical three-ounce paper cups (Dixie Bathroom Refill System, American Can Company, Greenwich, Connecticut) with a yellow heart design. The experimenters were instructed to go forth and find six real people without regard for the sex, age, color, or relationship of the real people to them. They were to set up the experiment in advance by placing the two cups upside down about one foot apart on a table. A nickel was placed under each cup. The experimenter then brought the real person into the room and gave him the following instructions: "What we're going to do is very simple. I want you to choose one of these two cups. Lift the cup you choose and, if anything is beneath the cup, you may take it and keep it. Go ahead."

After the first response was recorded, half of the real people were told to turn around and face away from the table (back condition). The experimenter simply replaced the cup upside down in its original position. For the other half of the real people, the cup was replaced upside down while the real person was watching (front condition). The real person's age was requested and recorded. The following instructions were then read: "Now I am going to let you choose again. I want you to choose one of these two cups. Lift the cup you choose and if anything is beneath the cup, you may take it and keep it. Go ahead." The response was recorded, and the real person was probed as to the reason for his second response.

The results were collected and tabulated. Under the back condition, of 40 real people, 16 alternated and 24 repeated. The response to the probe indicated that almost all real people in the back condition treated the experiment as a guessing game. In contrast, under the front condition, of 42 real people, 36 alternated and only 6 repeated. The chi-square comparing all four conditions (front versus back and alternators versus repeaters) was 23.03 ($df = 1, p < .001$). Of the alternators in this condition, most responded that they selected the alternator cup because they knew the other cup had

nothing beneath it. Of the repeaters, the most characteristic response was that some magic trick was being performed. The range of ages was 4-50 with very few below 12 and most above 17.

After having lost twice to subjects under laboratory and quasi-laboratory conditions with our elaborate black box, and having scored a partial success with children, we had finally achieved victory with "real people." Under the rule of selective selection of data, we concluded that our hypothesis was supported.

Our current research again calls attention to initial and boundary conditions that should, if not must, be included in any traditional learning theory if the predictive power of that theory is to be improved. The data (that part of which we choose to emphasize) do not challenge the bedrock of traditional learning theory. But they do loosen a few pebbles that stand at its base. One of perhaps many of the initial conditions that determine the predictive power of learning theory is the expectancy that the subject brings to the learning situation. If the suspicion of deception is minimized in the learning experiment, the probability will be increased that the experimental subject will generalize from his/her prior experience and consequently avoid an alternative where reinforcement has already been consumed. Why not?

As a combination of our experiences and experiments, we have varying degrees of confidence in the following hypotheses:

1. Learning theory does not account for the experience that a real person brings into a learning

situation. We believe that most organisms bring into a situation the hypothesis, based on prior experience, that once a reward is consumed or removed, given no other information, it will no longer be present on the next exposure. Furthermore, we believe one of the fundamental principles that an organism *learns* in any new situation is that reward *does* replace itself.

2. Learning theory, as presently stated, may only be applicable to utterly naive subjects.

3. There is no such thing as utterly naive subjects; there are only naive experimenters.

4. The college subject population is contaminated by expectancies of deception.

Distinguished Contribution for Applications in Psychology Award for 1973

Conrad Kraft

CITATION

For diligence, skill, and effectiveness in applying psychological principles and knowledge to improve the efficiency and safety of man's interaction with his environment and in complex man-machine systems. His experiments reflect both a sensitivity to problems stemming from the technological nature of our society and an appreciation for the potential value of the data and methods of experimental psychology. His ability simultaneously to encompass both points of view has produced a series of unique and important contributions. In particular, his development of radar room lighting systems and his identification of a visual illusion during night visual landing approaches as a major contributing factor to a series of fatal jet aircraft accidents represent outstanding examples of his and psychology's contribution to our society.

At the 1974 APA Annual Convention in Montreal, Conrad Kraft was honored as the first recipient of the Distinguished Contribution for Applications in Psychology Award. He received this award for his program of research, in particular his work in aircraft night visual landing approaches. He was presented with a citation of his formal contribution to the application of psychology and also with a check

for \$1,000. APA established this award in order to honor individuals who have pursued a systematic program of research that has had an applied impact.

The January 1974 *American Psychologist* incorrectly reported that Conrad Kraft was a recipient of a Distinguished Scientific Contribution Award. That issue carried his biography and list of scientific publications (pp. 32-36).

Proposed Bylaws Amendments

Nominations and Elections Committee and Election of the Board of Directors by and from the Previous Council

Nominations and Elections Committee

At the meeting of August 27 and 30, 1973, the Council of Representatives voted to establish a Nominations and Elections Committee to make nominations for vacancies on standing boards and committees of the Association, rather than the Board of Directors which makes such nominations under the current Bylaws. The following proposed amendments will transfer the responsibility for making such nominations from the Board of Directors to the newly established Nominations and Elections Committee.¹

ARTICLE VII

Section 8. The Recording Secretary shall be a Member of the Association, elected by the Council of Representatives, following nomination by the [Board of Directors] *Nominations and Elections Committee of Council*

Section 9. The Treasurer of the Association shall be a Member of the Association, elected by the Council of Representatives, following nomination by the [Board of Directors] *Nominations and Elections Committee of Council*

ARTICLE X

Section 1. The boards and committees of the Association shall consist of the standing boards and committees provided by these Bylaws and such other boards and committees as may be established in accordance with the rules of the Council of Representatives. Members of standing boards and committees, except those serving ex officio or as otherwise stated in these Bylaws, shall be elected for staggered terms by the Council of Representatives. The [Board of Directors] *Nominations and Elections Committee of Council* [may nominate a single person for not more than one-third of the positions on any standing board or committee and the Board] shall nominate at least two

persons for [at least two-thirds of the positions] *each position to be filled*. Additional nominations may be made by members of the Council of Representatives. Selections of members to committees other than standing committees and those reporting directly to the Board of Directors and Council of Representatives shall be the responsibility of the board through which the committee reports, with the approval of the Board of Directors. Except as otherwise provided in these Bylaws, each standing board and committee shall annually elect its own chairman. Standing boards and committees shall meet not less often than annually at the call of their chairmen. They shall report annually in writing to the Board of Directors and the Council of Representatives.

Election of the Board of Directors by and from the Previous Council

At the meeting of January 18-20, 1974, the Council of Representatives approved the following recommendation from the Board of Directors:

Amendment to Article VI, Section 1, of the APA Bylaws to provide that the election of the Board of Directors from Council is by and from the previous Council. This would not apply to the present Council. The rationale is that members of Council will have had at least one year to observe their peers in action prior to voting for the Board of Directors.¹

ARTICLE VI, SECTION 1

The Board of Directors shall consist of the President, the President-elect, the Past President, the Recording Secretary, the Treasurer, the Executive Officer (without vote), and six others elected by a preferential ballot by [the Council of Representatives from among its own members] *those members and from those members holding seats on the Council of Representatives during the year immediately preceding the election*. Directors not serving ex officio shall serve for staggered terms of three years. All members of the Board of Directors shall serve until their successors are elected and qualify.

Psychology in Action

COMMUNICATION WITH COLLEGE STUDENTS

HAROLD WEBSTER *Brooklyn College*¹

Longitudinal studies of college students undertaken in the 1950s and 1960s revealed systematic changes in attitudes, interests, and values. Intensive interviews and lengthy test batteries were employed. Changes observed during college may be summarized briefly as (a) increases in autonomy with respect to familial, educational, religious, and political institutions; (b) increases in impulse expression; (c) decreases in authoritarianism; and (d) increases in both anxiety and realism, particularly concerning future possible roles (Webster, Freedman, & Heist, 1962).

Theorists such as Sanford (1962) were quick to point out some implications for personality theory, two important ones being, first, that the ego growth reflected by such changes is sufficient to permit greater expression of impulses during college, and, second, that this ego growth may in time counterbalance infantile or neurotic personality trends. As important as these findings may be, I think that we have overlooked something of even more importance to be discussed subsequently.

Although we did not predict the specific nature of the student upheavals of the late 1960s, we were hardly surprised by them. We had already found serious disenchantment with cultural institutions. For example, in one study we had labeled the principal factor in an attitude change scale *rebellious independence* (Webster, 1958). Later it was found that the more militant students scored higher than others on such empirical measures of development. A covert, persistent trend had become overt in those students who became militant and in those who simply withdrew from the more general culture (e.g., drug users).

The alienation has been more severe than many psychologists would like to believe, for they themselves are often implicated now. Even a decade ago we had little trouble in collecting data compared to today.

Now the psychologist is often regarded as evasive or deceitful in communications with subjects. We often hear, "He pretends to be interested in one thing, but actually he is interested in something else." It is inferred that this "something else" may possibly be used to the subject's disadvantage.

We now resort to college committees that are set up to protect human rights. Malpractice insurance premiums are known to be increasing. Moreover, communication requires a *context*, and if the researcher seems to be identified with the current political establishment, then this increases the alienation. How far have we come in supporting a thoroughly paranoid society?

I see little need to document at length the fact that large numbers of subjects now distrust us. Attention should really be focused on what to do next. But in actual experience, during the past year I have seen graduate students lose their subjects in the following ways: Subjects (a) refused to be identified by name; (b) refused to return for additional testing; (c) asked for certain test material back and tore it up; (d) expressed fears of later blackmail; (e) said they thought that the researcher was testing only their consistency and truthfulness in answering questions; (f) compared answers even though politely requested not to; (g) complained that various tests, including ability measures, were "too personal"; (h) were unable or unwilling to read the items; (i) refused to answer items that they could not prejudge for meaning; (j) refused to give any data about family or friends.

Researchers themselves are coming to believe that such attitudes about giving data are of *primary* interest. Among those subjects who provided data without complaint, the majority were so passively dutiful that a colleague commented that they would "probably do absolutely anything if asked." This attitude is as problematical as the attitudes of the resisters. Co-operative subjects may want to provide the investigator with whatever they think it is that he is looking for. This is surely a far cry from the objectivity that once prevailed, or that we believed once prevailed, in data collection.

What can we do about this alienation, either from a service-oriented or from a research-oriented view-

¹ This article was originally presented in the symposium "The Revolt against Assessment—Where Do We Go from Here?" at the meeting of the Eastern Psychological Association, Washington, D.C., May 4, 1973.

point? It is *communication* for which better methods and theory are needed. Obviously, data collection is not mere information exchange, but communication at the most general level, the level that communication theorists refer to as *pragmatics*. Pragmatics includes both syntactics and semantics, but it goes beyond these to include the characteristics of the persons who communicate, especially as they are affected by communication.

Now a fundamental rule of communication is that it is supposed to be *true*. To assert by one means or another that one communicates falsely is a metacommunicative act that vitiates communication, such that the receivers become anxious, hostile, cynical, etc.

In human affairs deception never works, or never works for long. To prove a truth is admirable, but to prove that you can deceive is no achievement at all. Deception has been the easiest business of history. In order to study the conditions requiring deception, psychologists are confronted with a dialectic, which might be paraphrased, "How can you study the effects of deceit without being a deceiver?" The answer in my opinion is to study the truth about persons without deceiving them and without self-deception on the part of the researcher, to the extent that this is possible.

Efforts to induce subjects to compromise their principles, or efforts to deceive colleagues by sending them fake patients, can only have a double-edged-sword effect: You'll get it back, once the deception is revealed. Or your whole profession will get it back, as general mistrust and passive resistance. (How many practicing internists would send a person to a hospital with specific instructions to fake the symptoms of appendicitis, and then ridicule the colleague who unsuspectingly removed a healthy appendix? This kind of so-called research deserves to be censured by the profession, for it is clearly unethical.)

There is plenty of deviousness around to study without inventing more of it. A graduate student recently thought it necessary to harass subjects as one of the conditions in a study on the effects of frustration. Some of us went along with this scheme because of its apparent scientific merit. But I suspected (and said so) that most artificially controlled experimentation on human affective states (such as frustration) is a waste of effort and is possibly also an infringement on human dignity and freedom. Experimentally induced frustrations are not at all comparable to the natural and often severe kinds of frustration that affect most of us in our daily lives. We should ask ourselves whether studies of naturally occurring states have exhausted the possibilities of furthering our understanding of them before we embark on these artificial designs.

But lying is only one metacommunicative aspect of the extensive scientific problems of psychological communication. A great many more specific examples can be recognized in diverse research situations.

Metacommunicative phenomena (other than lying) include *Einstellungen* (from the psychophysics laboratories of the last century); rapport; many participation effects (e.g., volunteer, placebo, expectancy); the diverse mental test response biases; and coding-decoding values and conventions, including what to do with, that is, *how* to communicate with researchers, teachers, or psychotherapists. Even the "basic rule" of psychoanalytic practice ("Say everything that comes to mind, without exception") is metacommunicative, and so are the typical instructions to respond rapidly or uncritically to a personality inventory. Almost any situation in which information is collected or transmitted, verbally or nonverbally, is metacommunicative, which is actually the case for any social interaction. Lawyers know that there are rules of discourse, but for some reason psychologists are often unaware of these. It is this fact, the presence of significant metacommunicative effects, that we failed to take into account in the earlier studies of changes in student values, attitudes, and interests.

Twenty years ago a student might not respond to a test battery in the interests of "science," a motive that the staff thought was eminently compelling. But he usually did respond anyway because that was what everyone else was doing. Trust prevailed, and trust is a prerequisite for communication. Participation was voluntarism; that is, it was an act of will. I recall no poetic or Blakean types who said, "It doesn't feel right." But now the students *are* saying this, and I think that we had better listen.

But how shall we listen, or how *can* we listen, to students today? First, I think that *interviewing* has to be reinstituted into most research designs. In the past we never had much confidence in our tests anyway until we saw the substantial correlations with interview ratings. Of course, it is undeviating interviewing that I am advocating, that is, a semistructured kind of interview in which there is plenty of opportunity for the subjects to bring up their own personal orientations or problems. These problems easily come to subjects' minds, for example, in discussing particular test items. These kinds of interviews are also essential for self-assessment.

Second, inasmuch as communication is strongly influenced by context, we have to be aware of the changing values of those who provide our data. Rowe (1973) attributed the radical change over a decade in Peace Corps assessment procedures to the changing values of the subjects. He discussed a marked trend away from the use of traditional selection and assessment methods, a trend that brings the psychologist more into a counseling role and that permits more self-assessment by Peace Corps volunteers. This trend was recognized too late to avoid "turning off" thousands of potential Peace Corps applicants, who resented the traditional assessment procedures.

Third, we will have to develop better *theories* of

communication. For example, rapport used to be considered some kind of constant across subjects. We still find in individual testing reports the statement "Rapport was established." Now just what does this mean? "Rapport" in order to take a test and be admitted to or rejected from some treatment program? "Rapport" such that one gets a job or fails to get one with General Motors? "Rapport" to be accepted or rejected for hazardous duty or demanding service somewhere? If we research these metacommunicative effects, we may improve our understanding of our contemporary communication problems.

The theory of communication that is general enough to embrace intrapersonal as well as interpersonal processes has not yet been written down, but it surely will be. Most communication models of the past have erred in being excessively objective; that is, they have ignored intrapersonal processes. One very well known model, the psychoanalytic one, has, on the contrary, had great difficulty in moving from intrapersonal processes into a wider domain, in spite of the commendable efforts to explain phenomena such as transference.

Reusch and Bateson (1951) were among the first to move toward a communication theory of sufficient generality to be of service in theoretical psychology, and Bateson (1972) continued in this direction. Good theory is necessary for good practice, and vice versa. We may hope for more of both soon.

PSYCHOLOGICAL THRILLERS REVISITED

A TENTATIVE LIST OF "MASTER THRILLERS"

ARNOLD LeUNES *Texas A&M University*¹

The topic of supplemental reading assignments to accompany the more scientific materials presented in the undergraduate psychology course is not a new one. Of particular concern is the introductory course, a purported vehicle for "turning people on" to psychology. In this connection, McCollom (1971) presented a most intriguing list of what he called "psychological thrillers" to accompany the introductory course. This listing of 15 books was created essentially to illustrate the author's contention that hard science can be substantially

supplemented, as opposed to detracted from, by suggested readings of a "softer" and lower key variety. Taking McCollom's premise a step further, it would stand to reason that such a list, however tentative, could be drawn up to capitalize on the added knowledge, experience, and maturity of the beginning graduate student. Accordingly, the purpose of this article is to suggest a list of "master thrillers" for the more sophisticated reading audience that the psychology graduate student obviously represents.

Development of the Reading List

With regard to supplemental readings, personal experience has indicated that several points are noteworthy.

¹ Requests for reprints should be sent to Arnold LeUnes, Department of Psychology, Texas A&M University, College Station, Texas 77843.

One is that certain books seem to get significantly better reception than do others. Among them are those in which human behavior is presented by concerned parents, involved professionals, or sensitive writers with a flair for psychologically based character development based on their experiences with deviant behavior of various types. The graduate student particularly profits from this in that he has the freedom to integrate previous learnings and personal experiences into what is read. This, in effect, allows a brief book of 200 pages to become a psychological experience of considerable additional length. Perhaps this point alone is justification for a master thriller list, that is, the greatly increased opportunity to combine past and current scientific material with the reports of actual experience in the field. The crucial consideration here is a matter of appreciation somewhat analogous to reading *Huckleberry Finn* at age 15 and age 30.

A second point of worth bears on McCollom's contention, documented with carefully selected references, that you can lead a horse to water but you can't make him drink. In dealing with an often large and heterogeneous group of undergraduates, there is some tendency to require readings. With the graduate student, the inclination is to suggest readings based on the twin assumptions of higher motivation and increased homogeneity of interests.

Another emerging conclusion is the appreciation afforded brevity of expression. Many students, be they beginners or old pros, report that they are under heavy required reading pressures in most courses but would like to read outside materials of interest if they could be fitted into an already crowded schedule. Brevity should therefore be a virtue.

A fourth conclusion reached was that carefully selected readings can serve as potent reinforcers of current learning experiences, particularly if a variety of choices are made available and the element of punitive grading is held to a reasonable minimum. Few students would argue with this point.

Finally, student requests for stimulating supplemental readings run at a reasonably high level if the notion that such an option exists is put forward. Graduates and undergraduates alike vary little on this point, but the level of interpretative sophistication does. This, again, is the major justification for the master thriller listing.

Keeping in mind the aforementioned points of reader acceptance, simplicity of expression, brevity, reinforcement, and demand, a list of books was created for the use of beginning graduate students.

The Setting

The students in question were enrolled in the second half of a year-long proseminar series taught by six faculty members, involving, in separate five-week sec-

tions, sensation and perception, learning, physiological psychology, social psychology, personality, and abnormal behavior. The present readings represented 10% of the requirements of the final section on abnormal behavior, taught by the present author. The format for the book reactions was that they be couched in terms of the way the students would explain their feelings about a particular book if a friend were to walk up to them at a party and say, "Have you read——? What did you think of it?" One reading per week was required for a total of 5 from the 31 titles presented at the beginning of the section in the form of an annotated bibliography. An effort was made to soften the required nature of the assignment by placing it on an all-or-none basis; that is, read the book and write the brief informal report for weekly credit of 20 points or simply do not do it at all. There were no abstentions on the part of the class. The expectancy was that the readings would be done and the reactions would be of sufficient quality so as to preclude grading by degrees, and this assumption was borne out in performance.

The initial list of 31 titles has been abbreviated to include only the final 9 selections, and they are as follows:

MASTER THRILLERS

- AXLINE, V. *Dibs*. Boston: Houghton Mifflin, 1964.
- FRANK, G. *The Boston strangler*. New York: New American Library, 1966.
- GREEN, H. *I never promised you a rose garden*. New York: Holt, Rinehart & Winston, 1964.
- KESEY, K. *One flew over the cuckoo's nest*. New York: Viking Press, 1962.
- KEYES, D. *Flowers for Algernon*. New York: Harcourt, Brace, 1959.
- LINDNER, R. *The fifty-minute hour*. New York: Holt, Rinehart & Winston, 1955.
- PETER, L., & HULL, R. *The Peter principle*. New York: Morrow, 1969.
- SKINNER, B. *Walden two*. New York: Macmillan, 1948.
- VISCOTT, D. *The making of a psychiatrist*. New York: Arbor House, 1972.

In order to qualify for the preceding listing, each book was read by at least one person in six during the course and achieved a rating of better than 2.00 on the following rating system: 1, excellent; 2, good; 3, fair; 4, mediocre; and 5, poor.

It would seem appropriate at this time to discuss briefly the nine books. *The Making of a Psychiatrist* was a top selection despite a very late start and owed much of its acceptance to the analogous situation between what the students are currently undergoing and the travails mentioned by Dr. Viscott, the author, in his struggle to become a competent psychiatrist. His reflections on psychiatry and psychology were of particular interest to the group because most aspire to become clinicians themselves, and many have worked as undergraduates and as graduate students in mental health facilities of various types. The experience level of the group was sufficiently high to allow them to

incorporate their observations into the many provocative points presented by Viscott.

One Flew Over the Cuckoo's Nest was a top-drawer reading selection because of the character of McMurphy, the continual machinations of Big Nurse, the potentials for misuse of psychosurgery, electroshock therapy, and power itself, and the general tragicomedy tone of the book.

Dibs, the No. 1 thriller on McCollom's list, was also big among this readership. The characterization of Dibs and the gentle expertness of Dr. Axline made for a most satisfying reading experience.

The Boston Strangler was popular, in part, due to the question of how such a thing could have happened in the first place. The psychological phenomenon of gullibility and the other side of the coin, the con man, created quite a puzzle for these readers. They just could not readily believe that some of the approaches used by DiSalvo to enter the apartments of prospective victims would "sell." Quite obviously and unfortunately, they did.

I Never Promised You a Rose Garden was a reasonably popular choice, probably due to the vivid portrayal of the lead character by the author Hannah Green. The sensitivity with which the book was written was commented on several times. Few, however, were aware of the autobiographical nature of the story.

The possibility of biochemically induced higher intelligence and the innumerable problems encountered in moving progressively from mild retardation to superior intelligence made *Flowers for Algernon* a selection of fair frequency. Certainly, the earlier movie version of this book had been widely viewed and had gathered some appeal as a function of this medium and the interest generated thereby.

Those who read *The Fifty-Minute Hour* did so purportedly to acquire a greater familiarity with psychoanalysis. The case histories presented by the late Dr. Lindner were thought provoking and received good acceptance, but the analytic interpretation of them was questioned. Perhaps this is reflective of the prevailing mood with regard to psychoanalysis today.

Walden Two was a doubtful addition to the original list and was included almost as an afterthought. Certainly its relationship to abnormal behavior is tangential at best. However, laboring under the highly unsubstantiated assumption that no reading list is

complete without *Walden Two*, it was deemed worthwhile to include it. Accordingly, it was read by a third of the class, received rather good ratings, and met with general acceptance. It was a bit surprising that only another third had read the Skinner book prior to taking the course.

Another book with only peripheral concern to abnormal behavior was *The Peter Principle*. The decision to suggest this book arose out of a personal conviction, perhaps shared by others, that the mental health field is not without readily recognizable examples of the sort of inefficiency to which Peter and Hull address themselves. It was read by half of the class, and several students drew parallels between the examples of inefficiency mentioned therein and those they had personally observed in their experiences in mental hospitals, schools for the mentally retarded, or community mental health programs. Most, however, were more readily able to relate them to their immediate surroundings, namely, the university (using the university in a very broad sense because approximately 15 different universities are represented in the undergraduate experiences of the 18 participants). Several commented that the book was "cute," but not particularly illuminating for the purpose of scientific advancement.

Conclusions

Any conclusions drawn at this point must be highly tentative due to the embryonic state of the proposed idea. However, several points of worth seem clear at this time with regard to suggested readings. One is that beginning graduate students do welcome the opportunity to involve themselves in low-pressure readings of a type that allows them to integrate previous and current learnings. Second, there is a discernible thread of consistency that marks their interests in abnormal behavior, and these readings can constitute the beginnings of a master thriller list for students at that level. And the final conclusion to be drawn is that "soft" readings can complement the hard core of material in a scientific discipline such as psychology.

Comment

The Manpower Issue Revisited

Reactions to the special manpower issue of the *American Psychologist* (May 1972), for which I served as guest editor, fall in four areas:

1. Constructive suggestions for achieving a better fit between psychologists and jobs for psychologists, for improving psychology's information base, and for uncorking new employment opportunities for psychologists;

2. Criticisms of the special manpower issue—disappointments over the omission of certain groups of psychologists, problems not covered explicitly among the articles published, or demurrals with individual contributions to the issue;

3. Specific psychologists seeking help in entering the job market or in changing jobs; and

4. Praise to APA for producing, or to individuals contributing to, the special issue.

Among the promising proposals received is one suggesting that psychologists avail themselves of employment challenges abroad. Another adjures psychologists to create opportunities for enhancing the human condition through improving systematically—omitting, alas, criteria for determining what constitutes improvement—the way people behave in schools, on the job, and in society at large, the reason being that the development of programs for producing these improvements would spur jobs for psychologists at all levels. But unless proposals like these, and others, are nurtured beyond their present embryonic brainchild stage of abstraction they will surely die aborning, and this would be quite possibly a loss to psychology and to society.

Nonacademic Psychologists

Lament has been expressed over the failure of the special issue to analyze more explicitly the utilization of non-

academic psychologists. Needless to say, the time and resources for achieving this highly desirable coverage were simply unavailable. The decision was made, therefore, to get on with the special issue and to produce it earlier so that it might be of some value to the profession and to the public, rather than to delay its publication in order to enjoy a more perfect and more comprehensive—though a later and less immediately useful—set of articles. Retrospectively, it is my judgment that this decision will have proven to be in the better interest of the APA membership and of the publics we serve. Nevertheless, it should come as good news to these critics, as well as to psychologists in general, that a proposal for examining the feasibility of methods for studying the nonacademic utilization of behavioral scientists has been developed and is under consideration for support by a government agency.

While nonacademic psychology was not examined as exhaustively and directly as would in fact have been attempted had the resources been available, still the special issue cannot be faulted for *totally* overlooking this domain. Even though it was ineluctably gross, Cates and Cummings (1972) did provide a ratio of applicants to positions according to area for academic, clinical-counseling, and industrial research classifications. Freeman (1972) surveyed a variety of nonacademic rubrics—government, business, other, nonprofit, and self, and not academic employment exclusively. Sorenson's (1972) study of the income of industrial and organizational psychologists naturally included and was virtually dominated by nonacademic psychologists. The review (Wildman et al., 1972) of salary schedules of agency clinical psychology programs certainly involved nonacademic psychologists.

While it is regrettable (though for all practical purposes unavoidable) that stress was given to the academic

scene, it must be remembered that considerable attention was devoted (on the supply side) to psychology's students, a population including individuals many of whom eventually ply their wares beyond the groves of academe. Moreover, Speisman's (1972) sample study of the APA *Directory* revealed that 56.0% of America's psychologists are academically employed, a figure which is remarkably close to that of 56.6% which Freeman cites from the 1970 National Scientific Register of Scientific and Technical Personnel. The point is that, notwithstanding the fact that a hefty 44% of the nation's psychologists are employed in nonacademic settings—governments, schools (infra higher education), hospitals, clinics, community centers, business and industry, private practice, research centers, and elsewhere—data on the relatively more homogeneous 56% in academia were either more accessible or easier to generate than data on the more heterogeneous 44% in the foregoing nonacademic strata.

Independent, Private, or Group Practice

One reader grieved copiously because the special issue failed to embrace psychological manpower in independent, private, or group practice. Speisman's study revealed that 5.2% of us are in private practice. Employment data typically denote too that those who are self-employed command the highest salaries of all psychologists. On these two counts alone, then, while one may rue our explicit though not deliberate omission of psychologists engaged in independent practice, still I, as guest editor, cannot feel *that* remorseful by our failure to formally consider this 5% of the population of psychologists who, it must be added, don't do *that* badly financially.

Continuing, while we did not explicitly address ourselves to private

practice, we certainly did not exclude a variety of aspects of clinical psychology covered either wholly or in part in a number of articles. Since clinical psychology is the chief area of concern, generally speaking, to psychologists in private practice, this is still another reason why our exclusion of those in private practice does not strike me as a particularly unforgivable oversight.

Nevertheless, this omission will be remedied. APA currently has an HEW-funded project entitled Standards for Service Facilities. The project will examine the utilization of psychologists in agencies, institutions, and private practice. You private practitioners out there, are we forgiven?

The Vail Conference

Since publication of the May 1972 special manpower issue of the *American Psychologist*, a number of groups have addressed themselves wholly or in part to the manpower problem. Among these is the Vail (Colorado) National Conference on Levels and Patterns of Training in Professional Psychology.

The Vail Conference, sponsored by APA through an NIMH grant, brought together for a week in July 1973, over 130 psychologists and others concerned with training patterns, settings, and levels. The conferees were solicitous of the utilization of psychologists in a variety of environments. Perhaps foremost among these environments are those where the delivery of professional services is being supported by funds and employment opportunities no longer in great abundance so far as the more traditional fields of psychology—experimental and physiological, for example—are concerned.

At Vail, a number of resolutions were hammered out in plenary sessions following the development of recommendations by a number of task and interest groups. Of interest here are the resolutions bearing on manpower where, in particular, recommendations were made for modifying graduate (and undergraduate) training curricula so as to better pre-

pare students to apply for and function in those jobs which are available and which are reasonably expected to continue to be available as greater emphases in national priorities are invested in applied and socially relevant programs. It should be noted that professional psychology was defined at Vail as including all those subdisciplines within psychology which interface with the providing of services for individuals, organizations, or institutions—not only clinical and counseling psychology, but also personnel, prison, consumer, school, community, and other components of psychological science.

True, the Vail Conference, like others preceding it during the past quarter century, has no official status and hence no real clout with university training programs. Still, it is not unreasonable to assume that through the publications, symposia, workshops, and controversies it will have spawned, the Vail Conference will have at least a modicum of impact in making explicit for university and professional training programs opportunities and ways for better preparing students to consider and become marketable for positions which the society believes psychologically trained people can assume.

A Final Word

The question is frequently asked as to how a young person contemplating graduate work in psychology should be counseled. In view of job shortages, particularly in academic milieus, should the aspiring psychologist be dissuaded from majoring in a field where openings are reportedly scarce? Should the student opt, rather, for specialties where the job opportunities are greater? Perhaps he should not even go into psychology? Should graduate departments curtail those programs where the data suggest graduates will find the fewest job openings?

Naturally, the answer to these questions must be reached by the individuals or the departments themselves. But a couple of thoughts might be in order here. First, what

do you say to the person at the baccalaureate level who cannot get into graduate school? With selection ratios of, say, 30 applicants for one opening in a specified graduate program, many otherwise capable and promising students are unable to matriculate in a graduate program. A not unreasonable option for such a person is to look for a job in psychology, or for a job stressing the use of psychological skills or the application of psychological principles. Such jobs are available, though not necessarily plentiful, in community agencies, local and state government offices, and private industry. Is it not preferable for the baccalaureate psychologist to seek to satisfy his thirst for continuing in psychology by getting a job than to abandon altogether his interest in psychology when he is turned down by a graduate school? Given a year or two on this psychologically oriented job he might then wish to apply again to a graduate program, at which time he would probably have a sharper notion of the specialty within psychology in which he would like to concentrate. Or perhaps, be he a vigorous believer in and a promoter of psychology in his particular agency, he might have then developed a sufficient awareness of psychology's capabilities for helping to solve important problems so that the budget would have been acquired enabling him to hire a bunch of PhDs to work at his agency!

But considering those persons admitted to graduate school, it would be folly and perhaps cruel to inhibit a fledgling psychologist from specializing in whatever area of study he chooses, from tracking whatever direction his interests and motivations dictate, solely on the basis of a supply-and-demand ethic or manpower figures whose validity might be nil a few years hence. For example, it was not too long ago—maybe only four or five years back—when we were advised of the grave job shortages in engineering. Yet, today, according to a recent report (Hieronymus, 1972), this situation is changing dramatically; the demand for engineers is rising swiftly.

Even if the various predictions of widespread layoffs turn out to be true, it would seem that the most psychologically defensible course to follow would be that of advising the student of the facts as these are known by us today, but then after he is furnished the facts he should not be discouraged from majoring in any area that is congruent with his interests and talents, nor should he be admitted grudgingly into a program with the deflating caveat "Don't say I didn't warn you." The choice is that of the individual.

Finally, the experiences and hardships so many of our colleagues have endured in the last few years under score as nothing else can, the importance of having a broadly based graduate education capable of enabling the psychologist to shift gears more or less in tune with the vicissitudes of the economy and the ebb and flow of national priorities.

ROBERT FLANNERY

University of Pittsburgh

On O'Leary's "Fair Employment . . ."

Second author and editorial judgment were to have given say to an eager

ness to publish a timely article in the case of O'Leary (February 1970). Not that I disagree with the proposed view favoring work sample tests as predictors, but the presentation is superficial and the supporting evidence is meager. In fact, O'Leary combined anecdotes and speculations with an apparent lack of employment and selection process savvy. Is there an increasing tendency toward laxity (or arrogance) among us that by virtue of being experts unwarranted and sometimes unsupported expertise develops? Editors are responsible for weeding out speculations that masquerade as credible scientific pronouncements, though speculations are necessary research antecedents they are not the stuff on which conclusions should be based.

To be specific, there is the anecdote and absurd associated argument against using a valid selection instrument simply because the research showed that younger rather than older applicants are preferred. Yet a consequence of utilizing a valid selection instrument is that "a particular 62-year-old might do a much better job than a particular 35-year-old or many 35-year-olds, but will not be given the opportunity" (p. 147). What is the point? Forget the study results. Use the valid selection instrument sparingly. Combine the information obtained with the valid selection instrument with information from other sources. Research-based selection instruments, strictly are not perfect. After an other anecdote O'Leary stated that an application blank validated against tenure would not be useful for predicting job productivity. Should it? Honestly, very few researchers are surprised. If productivity-level predictions are desired, the research should be designed so that appropriate controls are included, for example, selection of subject, fulfillment of requirements, where is the evidence for the study acceptance of findings as effective predictors of job performance, and a quantity and quality of work.

A brief comment seems in order concerning the point that "The more

nearly the test duplicates the specific tasks to be performed on the job, the greater the chances of developing selection devices that are fair" (p. 148). It seems that valid would have been a better word than job, and though the logic is persuasive, without supporting evidence the contention is pure speculation; logic simply is not sought nowadays as a means of establishing fairness. The little evidence available on the topic (including some of my test validation research) indicates that some valid predictors approximating work sample tests are not necessarily fair for all job applicants. Work sample tests are, in fact, subject to the same fairness problems as are other types of predictors, and predictors need not necessarily be fair simply because they are valid.

There are sufficient exceptions to the conclusion that work sample tests are costly and difficult to apply to warrant a brief comment. Work sample tests for many jobs, especially clerical jobs for which filing, table reading, etc., are work samples, are no more costly to develop and administer than are other tests. When a company is willing to hire and train inexperienced job applicants—a practice certainly favorable to minority groups, costly high fidelity job simulations, especially where technical craft jobs are concerned may be unwarranted as well as limited in applicability and utility. O'Leary flippantly dismissed a serious flaw with one sentence: "The latter model penalizes those who are inexperienced applicants for a desired position, for example" (p. 149). Who, generally are the inexperienced?

Last, and probably least is the preposterous discussion of Type I and Type II error reduction through the application of work sample tests, preposterous because the jargon prevents out of place when α , β , N , and n (possibly missing) are missing. In an employment context more false and meaningful terms are false negatives and false positives or hits and misses. Nevertheless unless I have construed O'Leary's point given the same conditions the relative relative

ship between respective error types should maintain when cutoffs are raised or lowered irrespective of the type of predictor. Certainly fewer selection errors are expected for predictors with higher validity but when the conditions are equal, manipulating cutoffs will reduce one kind of selection error and increase another.

O'Leary Replies:

I will not waste the reader's time nor my own in responding to Gael's ad *Admirum* remarks. I would like however to examine some of the issues that he finally raises.

Predictive instruments are classifiable into three broad categories. The first can roughly be labeled *job simulation instruments*, which include assessment-center techniques such as in-basket management games as well as other content valid approaches like "skills" tests in typing and shorthand. These instruments are frequently referred to as "pieces of the job tests."

A second broad category of predictive tests could be labeled *intermediary tests*. Here the emphasis is on measuring some construct such as "intelligence," mechanical ability, or personal qualities like absenteeism or interpersonal assertiveness. This category involves measuring some quality judged necessary for the job and correlating these scores with some performance measure. This is where much of the psychologist's and personnel person's efforts have been placed when it comes to validation work.

Category 3 can be generally labeled *bi-data instruments*. It not only includes actually quantified bi-data blanks but also *scribble* interview forms and self-ratings. These are tied to some job criterion (e.g. turnover performance) on a purely actuarial basis frequently with little attempt to explain logically the relationship between predictor and criterion. However there is the compelling logic involved in the fact that past behavior is one of the most of effective predictors of future behavior.

Each of the three instrument categories has advantages and disadvantages. The thrust of my original article was that there was some merit in psychologists reexamining the advantages of job simulation techniques. A fundamental and practical issue here is utilization of professional time in validating selection devices.

The Civil Rights Acts of 1964 and 1972 as well as the *Griggs v. Duke Power* case (in which the U.S. Supreme Court unanimously ruled against the employer's use of a number of preemployment pencil and paper tests) have amplified the need to develop job-related selection devices. All three of the above test categories can demonstrate job relatedness through concurrent or predictive validities.

The question is one of long range efficiency in professional time utilization. As the demand for more valid selection systems justifiably grows and more people with the bare decision get rid of selection devices (O'Leary 1971) we face the possibility that all selection instruments will be recklessly and fruitlessly discarded. This subsequently enlarges and dramatizes the need for valid selection procedures. The need is widespread and calls for a substantial effort by selection specialists. This in turn calls for the most efficient use of validation time by psychologists working in the field. A predictive instrument that more closely approximates the job itself will usually have a higher probability of being a more valid predictor of job performance than an intermediary

type test simply because there are fewer non-job-related sources of variance. To repeat this is not a call for eliminating or downplaying the other selection device categories but a recommendation for a closer examination and awareness of the timely advantages of the job simulation approach.

In numerous situations the job simulation approach may be a more efficient solution. In addition the job replica approach may substantially reduce the amount of professional time wasted in looking for a frequently inconsistent performance criterion that accurately reflects job success. In these cases a systematic content validity approach using job simulation or a job replica may be most effective and more amenable to content validation.

Gael's first issue related comment is to point out that selection instruments simply are not perfect, and we should use valid bi-data results sparingly. This can be said about any validated selection device and indicates that Gael missed the point, namely that the article compared the advantages and disadvantages inherent in different selection approaches and was not a discussion of how one compensates for these disadvantages.

This is also true of his next comment regarding the production of turnover versus performance criteria using bi-data. Bi-data approaches have been more frequently used and requested in producing turn-over as a criterion than in producing performance. Again my comment was made to dramatize the specific advantages and disadvantages of particular bi-data.

In response to Gael's question: "Where is the evidence for the ready acceptance of bi-data as efficient predictors of job performance?" that a quantity and quality of work. I would encourage him to begin with my references in the original article. There he will find use of the most notable studies in this area. It was conducted at Standard Oil of Indiana by South A. Wright (1960) and (Jurns 1961). They predicted and

cross-validated success predictions on three measures of performance. Other successful and published studies include Lockwood and Parsons (1960), who used biodata items to predict performance of production supervisors, and Scollay (1957), who successfully used biodata to predict performance. These are just a few of the existing studies.

My statement regarding the greater probability of developing fair selection devices (devised having both content- and criterion-related validity) if we direct more effort in developing piece-of-the-job tests when appropriate, lead Gael to another comment: "and though the logic is persuasive, without supporting evidence the contention is pure speculation." Again, there is substantial evidence of the validity of job simulation techniques in specific hire and promotion situations. Again, I direct Gael's attention to my original reference list as a start. Bray and Grant's (1966) monograph is listed there, and there are many more reports of validated uses of the assessment center as one type of job simulation, including Bentz (1971) and Campbell and Bray (1967).

The disadvantage of the simulation approach to the inexperienced job applicant was acknowledged in the original article, and I reiterate my concern about it in as concise (rather than "flippant") a manner as possible. However, that concern should not immobilize one from constructive action. In many situations, the minority group members and the young who constitute a substantial proportion of the "inexperienced" group will have a better chance with a fairly run, job simulation method than an "off-the-shelf," verbally oriented pencil-and-paper test.

Finally, the commentator could more easily understand my discussion of Type I and Type II selection errors were he to look at the development of selection devices as a process. His comment suggested that he is, at the end of the whole process, comparing two validity coefficients—one from a job simulation predictor and the other from the "intermediary

tests" category. Under such conditions, and if both instruments have the same validity coefficients, cutoff movement will lead to similar increases and decreases in both types of error. I recommend that Gael back up in the process of instrument development to the point at which he is deciding what selection tools to use. A specific selection problem may be approached more effectively when one uses a job simulation method because the job simulation device will quite possibly have fewer non-job-related sources of variance (error) and, consequently, generate higher validities than the other approach.

The problem of validating selection tools has developed substantial proportions in today's society. The systems approach appears to be our best solution for attacking the selection validation issue at this time. This means using all three categories of predictive data previously described. My article (O'Leary, 1973) was an attempt to add some perspective to the solution by underscoring the content-validation advantage and the reduced need for inference that are frequently found in the job sample approach.

Job Samples:

A Better Approach to Selection Testing?

An important approach to selection testing has been given deserved emphasis by O'Leary (February 1973) in that he draws attention to the usefulness of content-validity considerations in the development of selection procedures. As the EEOC and OFCC guidelines force more and more employers to look carefully at their procedures, content validity will undoubtedly become a more prevalent and important technique. However, before accepting too quickly the notion that job samples are satisfactory content-valid predictors, and before claiming that "it is time for the profession of psychology . . . to communicate job simulation's significant advantages over traditional tests to test users [p. 149]," there are important considerations to make with regard to job sample tests. I would like to point out, first, some problems with O'Leary's presentation and, second, some important considerations that must be made about job samples.

The first problem with his presentation is that he stated the problem of individual exceptions to probabilistic predictions as if this is a problem peculiar to predictive and concurrent validity approaches. In fact, the problem of making nomothetical selection decisions which might be in error in individual cases is a problem of any imperfect decision scheme. Unless job sample tests are perfect predictors of job performance, they will also be subject to this problem.

The second problem with his presentation is that he switched criteria in midexample in order to show a "shortcoming" of the use of biographical data in selection. His example (p. 148) pointed out that biographical data validated against a criterion of turnover potential is not likely to be related to job performance on the task. Of course, that is true. However, if a task performance predictor was desired, that should have been used as the criterion in the first place. The failing in the example is not with the validity method, but with using data to predict something for which they had not been validated.

The final problem in his presentation was his statement that the use of job simulation tests as selectors would simultaneously reduce both Type I and Type II errors. That can only happen if the strength of the relationship between the job simulation and the criterion performance is stronger than the relationship between other predictors and the criterion. The relative strengths of these relationships is an empirical question, not one to be decided by a statement of faith that job simulations will reduce the non-job-related variance.

Psychologists who are faced with making decisions about the use of job samples in selection procedures should consider some additional points before accepting O'Leary's arguments (or the similar arguments of Wernimont & Campbell, 1968). First, there is the problem of bias in job sample tests. O'Leary mentioned this problem, but it did not dissuade him from exhorting psychologists to "speak out regarding the advantages of job simulation approaches [p. 149]." Though there is reason to believe that protected groups may be at a disadvantage on the performances required by many predictors, they are probably even less prepared to compete on job sample tests. For instance, if performance on a scholastic achievement test is used as a predictor, minority groups may be at a disadvantage because they have had (as a group) less educational oppor-

tunity. But their opportunities to gain experiences appropriate to performance on job sample tests are likely to be even more restricted than their opportunities to get educational experience! It is quite possible that the increased use of job sample tests will increase the bias of selection procedures.

The second consideration of job sample testing which psychologists should make is that a job sample is an ability test. It tells us what persons can do, not what they will do. Job performance is more than the possession of the necessary skills. It is the possession of the appropriate behavior patterns to utilize those skills. The best typist is not necessarily the one who typed with the greatest speed and the fewest errors during the employment test situation. It is the one who types with the greatest speed and fewest errors day in and day out while holding the job. The prediction of consistently good typing performance may be aided by predictors which do not look at all like a sample of the typing task.

Finally, the question of whether job samples have "significant advantages over traditional tests" is an empirical question. It will only be answered by determining our testing goals (lack of bias against protected groups, accuracy of prediction, etc.) and by empirically establishing the procedures which most nearly accomplish them. If job samples are best, then we should use them. If other predictors are superior in some situations, we should not discard them simply because they do not look like the job task.

MILTON R. BLOOD
University of California, Berkeley

O'Leary (February 1973) raised an important question but provided inadequate answers. The issue concerns the fairness and appropriateness of using certain biographical data (age, in the example on page 147; and suburbanite versus city dweller, on page 148) for empirical prediction even when such data are empirically valid. O'Leary then confused the argument by noting the idiographic or individual errors in such a situation. Of course, all decisions regardless of the variables on which they are based are uncertain predictions in which individual errors are made. The problem with using age, sex, race, place of residence, or other such variables as a legitimate basis for employment selection is not a question of psychometrics but of social values and public policy.

Suppose the rate of success among employees from minority racial-ethnic backgrounds is lower than the success rate among majority employees. Then racial-ethnic background is an empirically valid predictor of job performance under which majority applicants are to be preferred. The question remains whether employment selection on this basis is socially proper or even legal. Although great stress is put on empirical validity to justify selection procedures by both the EEOC (1970) and the old and new APA Standards (1966, 1973), empirical validity provides a necessary but not sufficient condition for an appropriate selection procedure. There should always be a preference for a more socially appropriate, empirically valid procedure over the procedure described above.

This leads us, as it did O'Leary, to concern with the content of the predictors used. Suppose Company W used racial-ethnic identity as a valid predictor of job performance in employment selection for forklift operators; Company X used a vocabulary test which was also empirically valid to select forklift operators; Company Y used tests of manual

dexterity and space relations which were also empirically valid; and Company Z used an empirically valid job sample test. Although each procedure will help in the selection of successful employees, there is considerable variability in the side effects of the procedures. Which of these procedures are legal and which are most socially desirable and in the public interest? This is not a psychometric question but one of social judgments.

We cannot escape the fact that we are forced to make value judgments about the appropriateness of predictor content and face validity. In our historical concern with objective, empirical evidence we have often tended to place greatest emphasis on the empirical, criterion-related validity of a selection process. And such validity is crucial, but it does not alleviate judgments about the quality and appropriateness of the content. Content validity is also crucial. In the present legal and social climate, content validity is also a necessary but not sufficient quality of an appropriate selection

process and is no less deserving of attention and concern than empirical validity. Perhaps to stress this importance, much more work is needed in the preparation of guidelines and procedures for assessing content validity.

O'Leary's concern with job samples lies in his judgment that such content is more socially defensible, and, within the bounds of practicality, I agree with him. However, job samples do not necessarily have anything to do with reduction of selection error as stated on page 148 (that is an unanswered empirical question), and job samples create their own set of special problems, some of which O'Leary noted in passing. In addition, there are good and bad job sample tasks just as there are good and bad assessments of other types.

In summary, O'Leary raised an important issue and then buried it in inappropriate psychometric arguments and overly optimistic and simplistic judgments about one type of content-valid approach. These failings should not detract, however,

from the issue of the importance of content-valid selection variables as we attempt to apply procedures in employment selection which are legally fair and socially proper.

Sprinthall & Sprinthall looks like a book.

But it's really a toolbox.

Yes, a toolbox. Designed by Richard C. Sprinthall and Norman A. Sprinthall. They call it **EDUCATIONAL PSYCHOLOGY: A DEVELOPMENTAL APPROACH**. And it's chock-full of high-utility items. Items made to work and work and work.

Like the vignettes. More than 20 altogether. They reinforce ideas and methods, textual maincurrents. Bring things together via a single personality. Be it Freud, Bruner, Skinner, Piaget or whomever.

Through imaginative graphics, the words take shape. Come alive. Become real. Cogent. More meaningful.

The supplementary materials provide even more tools. For the teacher. And the teacher-to-be.

In the Teacher's Manual each chapter summary is followed by suggested teaching

strategies. A selection of essay and discussion questions—answers included. And a test file of multiple choice questions (totaling over 750).

The Student Workbook also summarizes each chapter. And integrates it with preceding chapters. For self-study and diagnosis, objective multiple choice questions are given. Wound up by a reiteration of the chapter's key concepts.

Said one reviewer: "It is a book I personally feel I can identify with. The text presents important information in a way that will be meaningful to the new teacher."

Definitely.

And we've only scratched the surface. In fact, it's so loaded with workable, useful features, you'll probably agree that this book really is a toolbox.

Xerox Individualized Publishing is good for the fuel crisis. It conserves energy.

How does Xerox Individualized Publishing (XIP) save energy? Lots of ways. XIP lets you assemble a custom anthology with the help of our extensive catalog and trained editorial staff. Since you create exactly the Reader/text you want, you don't have to look further. Your students have all required materials in just one book. There is no limit to the amount of original material you may include, so you can stop running the duplicating machine overtime and put course outline, paper topics, comments, questions, or your own unpublished work all between one set of covers, in one printing. Our catalog lists and describes the best popular and scholarly articles and book excerpts in your field, so you don't have to burn the midnight oil finding them yourself. Our expert staff does all the work of retrieval and permissions, so you'll have time to ride your bike to campus and save gas. Since your students won't have to spend all that time in the Reserve Room anymore, maybe the Library can close an hour earlier.

So do your bit for the energy crisis. Become a XIP editor today. Fill in this coupon and mail it to us: Xerox College Publishing, 191 Spring Street, Lexington, Mass. 02173.

A good book gets better

The third edition of
Elements of Psychology offers you:

- **WIDE COVERAGE.** More than half the book now covers the areas of social, abnormal, personality, developmental, and intelligence. Material on learning, motivation, and emotion has been streamlined and brought up to date. Coverage of developmental and behavioral genetics has been integrated throughout the text. New topics include Altered States of Consciousness; Visceral Learning; Race, Genetics and IQ; Genetic Counseling; Biological Clocks; Psychosurgery; Morality, Aggression, and Equity.
- **AUTHORITY.** Current work and thinking on each subject is critically and carefully presented. Where needed, expert advice has been obtained (e.g. Dan Slobin on Psycholinguistics, Marjorie Honzik on Intelligence, Charles Tart on Altered States of Consciousness, Michael Lerner on Genetics, John Kennedy on Perception.)
- **180 BOXES — MOST NEW OR REVISED.** These examine the history of psychology, including classic experiments; frontier areas of research; and topics of unusual interest, such as the morality of mercy killing, cross-cultural correlation of child rearing practices to the amount of crime in a society, the ethics of psychological research on humans, competition and culture, terminal patients learning to accept impending death, the psychological basis of humor, and the causes of witchcraft.
- **SUPPLEMENTARY PACKAGE.** Semi-programmed student guide, with 2500 fill-in questions; behavioral objectives unit workbook, utilizing the Keller method of personalized instruction; behavioral objectives instructor's guide, with four mastery tests for each unit and 300 multiple choice examination questions keyed to the behavioral objectives for each unit; Instructor's Manual with 600 multiple choice test items in card form; glossary pamphlet free to each student.

DIVERSITY

From introductory psych to factor analysis, Saunders has the texts that meet your curriculum requirements.

**Leavitt:
DRUGS AND BEHAVIOR**

Ideally suited for undergraduate courses in psychopharmacology, this new text covers principles of drug action, drug effects on various types of behavior, the use of chemotherapy in disorders of emotional health, and the effects of various foods on behavior. Emphasizing a behavioral approach, the author discusses: drug toxicity, profiles of drug users, therapy for drug abuse, sensation and perception, learning and memory, and creativity. *By Fred Leavitt, California State University, Hayward. About 275 pp. Illustd. Ready late Summer. Order no. 5695.*

**Mikulas:
CONCEPTS IN LEARNING**

Here's a vital new text devoted to the practical implications of the various issues and principles of learning. The author synthesizes the major animal findings and concepts of classical learning and relates them to current research in human learning. Education, therapy, social issues, and self-understanding are carefully examined, along with the underlying bases of the physiology of learning. *By William L. Mikulas, University of West Florida. About 270 pp. Illustd. Ready August. Order no. 6327.*

**Hebb: 3rd Edition
TEXTBOOK OF PSYCHOLOGY**

This outstanding introductory text is known for its consistent, logical theoretical structure. The emphasis is on behavior and theory of learning with new material on mental illness; short and long-term memory; the chemistry of memory; and the latest research evidence on perception. *By Donald O. Hebb of McGill Univ., Montreal. 324 pp. 104 figs. \$8.50. March 1972. Order no. 4622.*

**DiCaprio:
PERSONALITY THEORIES:
Guides to Living**

Designed for courses in adjustment as well as personality theory, this valuable new text is strongly life-oriented. The author has organized his material to cover, in turn, development, learning, needs and motivation, conflict, and the "good" or "ideal" existence. In addition, he strongly emphasizes topics that foster an understanding of individual behavior and relate directly to effective living. *By Nicholas S. DiCaprio, John Carroll University, Cleveland, Ohio. About 500 pp. Illustd. Ready July. Order no. 3055.*

**Gorsuch:
FACTOR ANALYSIS**

Approaching factor analysis from an applied perspective, this new book presents component and common factor analysis as variants of the general linear (matrix) model. Special attention is given to: exploratory and hypothesis testing procedures, the replication of factors, utilizing computers and when to use factor analysis from mathematical and statistical models. *By Richard L. Gorsuch, Texas Christian University. 370 pp. Illustd. \$14.95. January 1974. Order no. 4170.*

**Torrey: 3rd Edition
A STUDY GUIDE FOR HEBB'S
TEXTBOOK OF PSYCHOLOGY**

This pre-tested manual will help the student develop his own analyses of the concepts presented in Hebb's text. Included are multiple choice questions (with answers), commentaries illuminating Hebb's major theses, and helpful bibliographic references. *By Charles C. Torrey, Macalester College. 142 pp. Soft Cover. \$2.95. March 1972. Order no. 8881.*

Sattler:
**ASSESSMENT OF CHILDREN'S
INTELLIGENCE**

Here's a definitive new text/reference that is both a practical guide as well as a research and clinical handbook for the individual intelligence testing of children. The text covers test administration, scoring, interpretation, report writing, and consultation. Special chapters are devoted to minority group children, the diagnostic process, childhood schizophrenia, mental retardation, organic brain damage, learning disabilities, and emotional disturbance. Tests covered include the Stanford-Binet, WISC, WPPSI, PPVT, CMMS, Leiter, Quick, PTI, and Slosson. Over 1200 studies are reviewed. Instructor's Manual of test items available. By **Jerome M. Sattler**, *San Diego State University*. 526 pp. \$13.95. January 1974. Order no. 7943.

Rosen, Fox & Gregory: 2nd Edition
ABNORMAL PSYCHOLOGY

An unusual, intriguing text for undergraduates. Integrates psychoanalytic theory, experimental psychology and practical clinical experience with relevant research in related fields. Difficult and often controversial subjects are handled from a wide range of viewpoints. And every chapter in this second edition has been thoroughly rewritten and revised. By the late **Ephraim Rosen** of the Univ. of Minn., **Ronald E. Fox** and **Ian Gregory**, both of Ohio State Univ., 516 pp. Illustd. \$11.50. March 1972. Order no. 7696.

Millon: New 2nd Edition
**THEORIES OF PERSONALITY &
PSYCHOPATHOLOGY**

This book offers students the opportunity to read the actual writings of major psychologists rather than just reading about them. The author groups the major theories of abnormal psychology by the kinds of data they emphasize—*biophysical, intrapsychic, phenomenological* or *sociocultural*, and then presents representative papers in which leading theorists of each school (such as Sheldon, Freud, Rogers, and Skinner) discuss the etiology, pathology, and therapy of abnormal behavior. Edited by **Theodore Millon**, Univ. of Illinois. About 500 pp. Illustd. About \$5.95. Ready April. Order no. 6382.

Millon & Millon:
**ABNORMAL BEHAVIOR AND
PERSONALITY**
A Biosocial Learning Approach

This informative, eclectic undergraduate text is ideally suited to the student's first course in abnormal psychology. The authors strongly emphasize the development of personality characteristics—they impart the knowledge by skillfully drawing on the student's familiarity with the psychologically relevant experiences encountered in daily life. They examine all viewpoints, and their treatment of the subject matter is unusually wide-ranging. Elucidated are all approaches to abnormal behavior—the behavioral, psychoanalytic, phenomenological, biophysical, and sociocultural. A workbook to accompany this text will soon be available. By **Theodore and Renee Millon**, both of the University of Illinois. About 500 pp. Illustd. Just Ready. Order no. 6390.

Johnson:
**AGGRESSION IN MAN
AND ANIMALS**

This valuable supplement for any undergraduate course in psychology cuts across disciplinary lines to present a broad-based treatment of all aspects of aggressive behavior in man and animals. The author discusses aggressive tendencies and behavior in more than 150 species. He also probes current social problems in depth and detail. By **Roger N. Johnson**, Ramapo College of New Jersey. 269 pp. Illustd. Soft Cover. \$3.95. April 1972. Order no. 5160.

Whittaker:
**RECENT DISCOVERIES IN
PSYCHOLOGY:**
Readings for the Introductory Course

An exciting new supplement designed to stimulate and involve the student. Every article in this relevant new reader was written within the last ten years. Covered in detail are topics such as invasion of privacy in the investigation of human behavior, perception and judgement in the political extremist, the adolescent "hippie," and psychological alternatives to war. Edited by **James O. Whittaker** of Penna. State Univ. 448 pp. Soft Cover. \$5.50. January 1972. Order no. 9325.

W. B. SAUNDERS COMPANY
West Washington Square, Philadelphia, Pa. 19105

Millon:
MODERN PSYCHOPATHOLOGY

This stimulating text for the first course in abnormal psychology captures the student's interest because it pays particular attention to the conditions most familiar and important to him—the milder pathological syndromes. These disturbing but not disabling disorders, which the student will recognize from his own experience, are presented in such a way that they help the student to understand the major syndromes. Psychopathology is seen as a coherent continuum, ranging from the mildest deviations from the norm to the most severe psychotic states. By **Theodore Millon**, Univ. of Illinois. 681 pp. Illustd. \$10.75. Sept. 1969. Order no. 6385.

Skinner: NEUROSCIENCE:
A Laboratory Manual

A comprehensive introduction to the neuroscience laboratory for the psychology student. Shows how the neural elements of the brain work and how they operate together in systems. Describes techniques for experiments on the brain, including stereotaxic surgery, sites for histological examination, and construction of Intracranial Implant devices. By **James E. Skinner** of the Baylor College of Medicine. 244 pp. 211 figs. \$6.95. Soft Cover. April 1971. Order no. 8345.

Stotland & Canon:
SOCIAL PSYCHOLOGY,
A Cognitive Approach

Here is a new, provocative text which examines the way in which we are "programed" by experience to react and respond to various and varied life situations. Essential principles are presented and applied to areas such as interpersonal perception, communicational learning, conformity, self-esteem, and action and decision. By **Ezra Stotland** and **Lance Canon**, both of the Univ. of Washington. 592 pp. Illustd. \$11.95. September 1972. Order no. 8608.

Singer & Singer:
PSYCHOLOGICAL DEVELOPMENT
IN CHILDREN

This basic text in child psychology presents a unique synthesis of chronological and theoretical approaches within a unified viewpoint. The authors have placed their major emphasis on the processes of the child's development. They show how children acquire language, learn moral judgements, become socialized. Thus, it builds an understanding of why children develop as they do. By **Robert D. Singer** and **Anne Singer**, both of the Univ. of Calif., Riverside. 437 pp. Illustd. \$8.00. Oct. 1969. Order no. 8310.

Wallace:
PSYCHOLOGY: A Social science

This highly contemporary text offers a real alternative to the traditional survey approach to introductory psychology. Focuses on human psychology as a Social Science and discusses such topics as: racism in America, the ecological catastrophe, alienation, violence, population growth, manipulation and power and much more. By **John Wallace** of the Univ. of Calif., Irvine. 429 pp. Illustd. \$9.50. January 1971. Order no. 9115.

Hardyck & Petrinovich:
INTRODUCTION TO STATISTICS
FOR THE BEHAVIORAL SCIENCES

An ideal introductory statistics text for students with little or no math background. The authors develop in clear detail the procedures of descriptive statistics upon which inferences are based. Each chapter includes a set of problems, and examination questions are provided in an accompanying Instructor's Manual. Also available is a WORKBOOK to accompany the text. By **Curtis Hardyck**, Univ. of Calif., Berkeley; and **Lewis Petrinovich**, Univ. of Calif., Riverside. Text: 302 pp. Illustd. \$7.50. Oct. 1969. Order no. 4520. Workbook: 118 pp. Illustd. Soft Cover. \$3.50. Oct. 1969. Order no. 4522.

"A generally superior textbook...
recommended for introductory courses in social psychology."

*from a review of the first edition in the *American Sociological Review*

An Introduction to Social Psychology Second Edition

James A. Schellenberg, Western Michigan University

A concise, basic text which explores and reviews the major topics in social psychology.

- **Builds on a framework of case histories and experiments**, providing basic grounding in social psychology.
- **Theoretical and methodological pointers**, separated from the main body of the text, provide background and highlight key ideas at the most significant point in the presentation.
- **General organization — Seven topics.** The material is grouped around seven general topics: affiliation, aggression, social influence, attitudes, groups, social norms, and personality in society. Each section contains four chapters and concludes with a review and discussion chapter. A glossary of key concepts is included along with a bibliography and **Instructor's Manual** with a large supply of essay, multiple choice, and true-false questions.
- **Major points of revision.** The section on "Culture and Personality" is expanded into a full, four-chapter concluding section with treatment of culture, psychological ecology, and contemporary issues of individual identity. A brief, final chapter on "Research: Theory and Practice" has been added; and major new materials are found in chapters on altruism ("Helping People"); attraction ("Liking People"); interpersonal perception ("Perceiving Persons"); and social identity ("Individuality in Contemporary Society").

AMERICAN PSYCHOLOGIST • MARCH 1974 • 7a

What is the driving force in human behavior? What determines our individuality?

Help your students explore the mysteries of the mind with these outstanding books from Prentice-Hall...

THEORIES OF LEARNING 4th Edition, 1974

Gordon H. Bower and Ernest R. Hilgard,
both of Stanford University

One of the most widely used advanced level texts in psychology, the new edition of **THEORIES OF LEARNING** provides your students with thoroughly updated information on learning theory's main influences and contemporary research. The authors have added a discussion of the philosophical background of learning theory and examine various questions of epistemology. Retaining the chapter structure of earlier editions, Professors Bower and Hilgard devote individual chapters to fresh new analyses of the relevance to contemporary research of the work of such important figures as Freud, Hull, Pavlov, Guthrie, Skinner, and Tolman. Other new materials include behavior modification, technologies of instruction, psycholinguistics, computer simulation, and biofeedback and visceral learning.

June 1974 approx 700 pp. \$9.60

PSYCHOLOGY: An Introduction

Charles G. Morris, University of Michigan

Now in use at a wide variety of schools, this successful text surveys the essentials of psychology from classical theories to current trends. **PSYCHOLOGY: An Introduction** gives students an awareness of the scope and content of psychology, a working knowledge of its vocabulary, and an understanding of its research methods. Because the author defines his terms in context, no chapter depends on preceding chapters, and the instructor can order the topics to suit the students' needs. Study aids include an outline at the beginning of each chapter and a summary at the end. Boxed inserts analyze special topics, such as major contemporary issues. A Study Guide-ACCESS Workbook reinforces the text. A Teacher's Manual is available.

1973 641 pp. cloth \$9.95

Study Guide Access Workbook \$3.60

ELEMENTARY PRINCIPLES OF BEHAVIOR

Donald L. Whaley, North Texas State University
Richard W. Mallot, Western Michigan University

Reinforcement theory demonstrates that learning need not be painful or boring. Bearing this in mind, Professors Whaley and Mallot have constructed an unusual general psychology text that helps students enjoy learning psychology without sacrificing necessary rigor. The text features a "living content" by incorporating studies on the application of behavioral analysis to human affairs. The authors use an informal style to avoid the language barrier that sometimes creates communication gaps between faculty and students. Readings are presented in order of increasing complexity, and are class-tested for clarity and proper pacing. A valuable core text or supplement to courses in learning and introductory psychology.

1971 454 pp. paper \$7.15

BEHAVIOR PRINCIPLES 2nd Edition, 1974

C.B. Ferster, American University
Stuart Culbertson, American University
Mary Carol Perrott Boren, Walter Reade Army Institute
of Research

Extensively revised in this new edition, this successful text continues to serve as one of the most comprehensive available books about principles of operant behavior. And now **BEHAVIOR PRINCIPLES** is an even more effective teaching tool, with various new features to satisfy the student's need for relevance, and better teaching procedures for using the book. New to the chapters on the principles of human behavior are "real world" examples of psychological phenomena for the student to analyze. Increasingly complex behaviors are presented to coincide with the student's increasing technical sophistication. Also new to this edition is an extensive behavioral analysis of depression and a discussion of relevance of behavioral principles to other fields in psychology and to other disciplines.

September 1974 542 pp. price forthcoming

THE PSYCHOLOGY OF HUMAN DIFFERENCES

Leona E. Tyler, University of Oregon

The study of human differences is an evolving science, and Professor Tyler charts the major directions of recent research. The book itself comprises three parts: first, a section about dimensions of individual differences examines such factors as intelligence, school achievement, personality, special talents, interests and values, and cognitive style. Second, in a section on group differences, the author discusses variables related to sex, age, race, and social class. Finally, the book concludes with an examination of the factors producing individual differences.

1965 572 pp. \$8.60

EXPERIMENTAL PSYCHOLOGY 2nd Edition

Benton J. Underwood, Northwestern University

Covering a broad range of subject matter and methodology, Professor Underwood integrates content and methods, and presents meaningful research that students can perform with a minimum of equipment. Among the topics the book examines are perception, designs using independent groups, learning and forgetting, and problem solving. Written for the student, **EXPERIMENTAL PSYCHOLOGY** is based on the author's several years of teaching experience. Students can readily understand the factual matter presented without knowledge of statistics. This revision also helps students sharpen their critical faculties by citing examples of poorly executed experiments.

1966 678 pp. \$10.00

A New, Fresh Approach to Introductory Psychology

UNDERSTANDING HUMAN BEHAVIOR

by James V. McConnell of the University of Michigan

Comprehensive, dramatic introduction to principles of psychology emphasizing positive, constructive and rewarding approach to learning.

Human behavior analyzed from three points of view: *intrapsychic, biological, and social/behavior.*

Fictionalized case histories, experiments and illustrative stories provide intriguing preview of chapter content. Topics include: Sperry's split-brain work, Rosenhan's work on accurate sanity diagnosis.

Personal and social concerns fully developed in both textual and fictional material. Topics include: biofeedback, Transactional Analysis, human sexuality.

Research experiments presented from point of view of experimenter (why he/she planned it that way) and the subject (how he/she perceived the experiment).

Running glossary contains definitions of psychological terms, more difficult everyday words, related references, author's comments, and chapter summaries.

REVIEWER COMMENTS:

"I was immediately struck by the high readability of the chapters and the fictional vignettes beginning and ending each chapter. There is little doubt that J. V. McC. has apprehended his goal: an introductory psychology text written for all students."
Elliot Entlin, Ohio University

"Overall, I would have to say that the work is very thorough, scholarly and well written, giving significant concepts in a generally interesting manner. It should appeal to students at a variety of intellectual levels."
Robert Hoepfner, Orange Coast College

"My general impression is that you've got a winner."

Charles G. Halcomb, Texas Tech University
720 Pages/February 1974/\$10.95 (tentative)

Also Available to Accompany the Text—

STUDENT MANUAL by Lawrence Al Siebert, Oregon State System,
and Timothy Walter, Rhode Island College

Provides a complete review of the textual material, a series of "prescriptions" on how to study and how to pass exams, detailed step-by-step reviews of chapter material, true-false test questions, individual action projects, and readings.
128 Pages/February 1974/\$2.50 (tentative)

INSTRUCTOR'S MANUAL by Lawrence Al Siebert and Timothy Walter.

Includes chapter summaries, content objectives (major learning points), list of films and sources, and suggested class demonstrations.
96 Pages/February 1974

TEST ITEM FILE BOOKLET by Lawrence Al Siebert and Timothy Walter.

Over 900 true/false and multiple choice questions laid out for easy assembly as a card file.

AMERICAN PSYCHOLOGIST • MARCH 1974 • 11a

Everything about Audrey and Dick's **FUNDAMENTALS of PSYCHOLOGY** is real, including the two people who conceived it, wrote it, edited it, and lived with it for three years.

FUNDAMENTALS OF PSYCHOLOGY has something that no other introductory psychology book has.

Audrey: "Us! Two who also happen and teachers."

professional psychologists to be very good writers

FUNDAMENTALS OF PSYCHOLOGY is a breakthrough book. A return to basics. Good writing. Good scholarship. Good teaching. And it was written from beginning to end by two professional psychologists, Audrey Haber and Dick Runyon.

Audrey: "We wanted to do a book that makes psychology mean something to students—something real."

Dick: "We wanted to do for introductory psychology what we did for statistics."

In the past, professional psychologists and ghost writers have teamed together to write introductory psychology books that never really hung together.

Dick: "Not our book! I even Audrey and her husband at a time while we were on it . . ."

lived with for months working

Audrey: "It definitely wasn't a case of 'you write a chapter, I write a chapter.'"

The result is a book that sounds like one person wrote it. One person who knew the subject inside out, and knew how to keep things interesting and clear, without any distortion.

Audrey: "Our book is loaded with case studies and real life examples . . ."

Dick: "And wait'll you see the exciting

excerpts from articles and books we've put in our special 'Issues' sections . . ."

Audrey: "Even some stuff on Kung Fu . . ."

But, don't let this modern style worry you. This book's strong on research. Meticulously accurate, even at its most entertaining.

And there's no end of learning aids. Mini-glossaries and annotated bibliographies at the end of every chapter. A complete glossary in the Student Workbook.

Audrey: "Summaries

Dick: "And a workbook the text!"

all over the place . . ."

that really works with

FUNDAMENTALS OF PSYCHOLOGY. It's what introductory psychology books have been becoming. Only Haber and Runyon is—right now. Can Audrey and Dick describe their book in one word?

Audrey: "Great!"

Dick: "Personal."

Publisher's Note: The authors are, of course, biased, but the book is not.

CAN YOU BELIEVE WHAT THEY'RE SAYING ABOUT KENDLER

They're saying that Howard Kendler's Third Edition of **BASIC PSYCHOLOGY** is even better than the Second Edition.

They say it emphasizes the scientific method in the context of relevant human experience, integrating three main themes: (1) The study of psychology must be based on evidence, (2) All major principles and psychological theories should be fairly represented, and (3) Psychology should be

studied in relation to meaningful social issues.

We say, decide for yourself.

Write today for a complimentary copy of **BASIC PSYCHOLOGY**,

Third Edition. Upon request, we'll also enclose the supplements:

STUDY GUIDE for **BASIC PSYCHOLOGY** by Tracy Kendler and the **UNIT WORKBOOK** for P.S.I. by Jeffrey Corey and James McMichael.

TWO WORKSHOPS IN THE RORSCHACH METHOD

Case Western Reserve University
Department of Psychology

Summer Session, 1974

Conducted by
Marguerite R. Hertz, Ph.D.
Professor of Psychology

Workshop I. BASIC PRINCIPLES

June 17-21

Technique of administration. Fundamentals of scoring. Psychological significance of test variables. Introduction to interpretation. Clinical demonstrations in hospitals.

Workshop II. ADVANCED CLINICAL INTERPRETATION

June 24-28

Analysis of cases presenting a wide variety of disorders. Review of newer developments in test interpretation. Clinical demonstrations in hospitals.

All-day sessions, 9:00 a.m.—4:00 p.m. (plus one evening session). Fee for each workshop: \$109

For psychologists, psychiatrists, counselors, and qualified graduate students in psychology and related disciplines. For Workshop II must have had at least one prior course in Rorschach professional experience.

Certificates awarded for satisfactory completion, and one unit of graduate credit available for each workshop.

Enrollment limited

THE MIDDLEBROOK SPOT

It's only four months old, but Patricia Niles Middlebrook's
SOCIAL PSYCHOLOGY AND MODERN LIFE
is fast becoming the leading text in its field. Here's why:

"Middlebrook relates everyday experience with hard core lab studies of social psychological phenomena. It's hard to find these two together without the loss of some information. But **Middlebrook accomplishes this flow that most books do not.**"—*Carl Greenberg, Wayne State University*

"It's very good."—*H. C. Triandis, University of Illinois*

"I am very impressed with Middlebrook's ability to integrate the very latest research findings in so many areas. The chapter on altruism is quite well done and an important addition."—*Ronald L. Cohen, Bennington College, Vermont*

"An authoritative and well written presentation of social psychology for undergraduates. The book should become a **classic in its field.**"—*John R. Silvestro, State University College at Fredonia, New York*

"**Most dynamic text I have reviewed:** uses every technique and feature to encourage and motivate students to read not only text but do further research."—*Cecil P. Jones, Daytona Beach Community College, Florida*

"A **creative, lively, and integrative** book with **high readability** and **coverage of relevant topics.** Students will find it intriguing and thought provoking."—*Raymond F. Paloutzian, University of Idaho*

"I had already chosen another text before I received the book you sent. I was **sufficiently impressed** with it **to revise my order.** The section on altruism particularly is as comprehensive and up to date as one could hope for."—*Ira Silverman, University of Rhode Island*

More than 150 outstanding
authorities are ready
to talk to your
students...

UNIVERSITY PROGRAM MODULES from General Learning Press are original short works offering your students the benefit of authoritative discussions of vital issues by recognized experts. Versatile, timely, and low in cost, they bring a new kind of in-depth instructional material to the college classroom.

Among our most recent modules...

Theodore X. Barber, The Medfield Foundation, Inc.
Martin W. Ham, The Medfield Foundation, Inc.

"Hypnotic Phenomena"

Norman L. Farberow, Veterans Administration Wadsworth Hospital Center
"Suicide"

Marvin R. Goldfried, State University of New York, Stony Brook
Joyce Sprafkin, State University of New York, Stony Brook
"Behavioral Personality Assessment"

Darwyn E. Linder, Arizona State University, Tempe
"Personal Space"

Edward E. Jones, Duke University
Camille Wortman, Northwestern University
"Ingratiation: An Attributional Approach"

O. Ivar Lovaas, University of California, Los Angeles
"Behavioral Treatment of Autistic Children"

The first thing
we did with our
Human Development
series...

Was to find
a good-looking hero.

You see, our film strip series deals with real people—not cartoon characters. And through these real people you are offered a challenging look at the first 2½ years of life—the crucial years.

Effects of day care centers . . . sequence of language acquisition . . . effects of sensory stimulation on intellectual and emotional development. Human Development offers a provocative Old-vs-New cross-section of the theories and findings of the most noted authorities, including Piaget, White, Kagan and Bower.

Designed for students of education, psychology, home economics, and the social sciences, Human Development is far less expensive than movies—and far too important to overlook.

Human Development — The First 2½ Years

FOR THE HUMANISTIC APPROACH

Psychology of the Arts

Hans and Shulamith Kreidler. "A field of exploration can be said to have established itself as a discipline when the range of its subject matter and the principles of its procedures and interpretations are laid out in a sufficiently systematic and complete way. By this criterion [*Psychology of the Arts*] may well claim to have established the psychology of the arts as a discipline. . . . The present work will remain the standard text for some time to come." Rudolf Arnheim, *Contemporary Psychology* \$13.75

Text Price: \$12.50 (adoptions 5 or more copies)

Normal Aging

Reports from the Duke Longitudinal Study, 1955-1969

Erdman Palmore, editor. "A milestone in the field of gerontology and geriatrics. . . . A must as a reference for all disciplines that are concerned with the study of human aging." *Choice* \$10.75

INTRODUCTION TO EXPERIMENTAL PSYCHOLOGY, Second Edition

Douglas W. Matheson, *University of the Pacific*, Richard L. Bruce, *University of Alaska*, and Kenneth L. Beauchamp, *University of the Pacific*

Designed to prepare the beginning student to undertake independent research, this text provides an introduction to the philosophy of science, experimental methodology (including control and sampling), basic research design, laboratory equipment and techniques, statistical analysis, and the preparation of reports and proposals. As in the first edition, the approach is to allow students to learn by doing which includes performing experiments as part of their research project. Major changes in the second edition: a new chapter on analysis of variance; the fully revised procedures chapters (experimental techniques and tools); a section on the research project; a section of student research projects; and prose chapter content summaries.

Instructor's Manual Available

February 1974/512 pages/\$10.50 (tent.)

SYSTEMS AND THEORIES OF PSYCHOLOGY, Third Edition

James P. Chaplin, *St. Michael's College*, and T. S. Krawiec, *Skidmore College*

SYSTEMS AND THEORIES OF PSYCHOLOGY presents systematic psychology as an evolving field in which contemporary theoretical formulations are related to their origins in historical schools and systems. The third edition reviews contributions from the ancient Greeks, the British empiricists, nineteenth-century physiology and psychology, the recent developments and the schools of the twentieth-century. Topical in its organization, this revision includes additional material on theories of social psychology, psycholinguistics, existential and humanistic views of psychology, and ethology.

Test Items Available

February 1974/768 pages/\$11.00 (tent.)

INTRODUCTION TO ENVIRONMENTAL PSYCHOLOGY

William H. Ittelson, Harold M. Proshansky, Leanne G. Rivlin, and Gary H. Winkel, *all of the Graduate Center, City University of New York*, and David Dempsey, *Editorial Associate*

This is the first and only available text designed to serve as a comprehensive and up-to-date introduction to environmental psychology. The book's interdisciplinary approach to the field and its problem areas reflect the nature of our understanding of complex human behavior through the analysis of man's relationships to his environment. The text has been designed for use by students in psychology, architecture, education, design, sociology, urban studies, and geography departments. Also available—a supplementary collection of readings.

March 1974/408 pages/\$9.95 (tent.)

STATISTICAL ANALYSIS, Fourth Edition

Allen L. Edwards, *University of Washington*

For the student with a limited background in mathematics, this book demonstrates the ways in which elementary statistical theory and methods can be used toward the solution of problems in psychology and other behavioral sciences. Proofs are de-emphasized in this edition, and illustrations are employed to promote the understanding of the meaning of statistical theory. New problems and exercises involving simple calculations are provided for each of the chapters, with the answers to numerical problems available at the back of the book.

January 1974/288 pages/\$8.95 (tent.)

LEARNING AND THE CONTROL OF BEHAVIOR: SOME PRINCIPLES, THEORIES, AND APPLICATIONS OF CLASSICAL AND OPERANT CONDITIONING

Edited by David A. Lieberman, *University of Illinois*

Beginning with the basic assumptions underlying experimental research, this collection of readings examines the major principles and theories of classical and operant conditioning and their applications to the real world. Offering a balanced presentation of both cognitive and S-R/behaviorist theories of learning, each chapter is preceded by a lengthy introductory essay which provides historical background for the readings and their significance as well as a discussion of the moral issues raised by the efforts to control behavior.

What do you look for in an introductory text?

1. Have you avoided using a traditional, eclectic, cover-every-topic book?
2. Would you like your students to apply what they learn in your introductory course to contemporary psychological issues?
3. Are you looking for a book which covers dreaming, drugs, ecology, the unsafe society, communes, aging and death, new variations in psychotherapy, all coordinated with basic psychological theories, studies and concepts?

If you can answer yes to these three questions, you'll be interested in our new introductory psychology text:

SOCIAL PSYCHOLOGY

Issues and Insights/2nd edition

GOODWIN WATSON, *Columbia University*, and DAVID W. JOHNSON, *University of Minnesota*

This edition offers increased emphasis on the application of social psychological knowledge to the solution of current social problems, and will appeal to instructors who seek a current alternative to texts that principally stress theory and research. Approximately half the material in this edition is new. *Instructor's Manual*.

475 pages/1972/paperbound \$6.95

CONTEMPORARY SOCIAL PSYCHOLOGY

Edited by DAVID W. JOHNSON, *University of Minnesota*

The editor seeks to demonstrate that well-validated social psychological theory can be applied effectively to the solution of social problems and improvement of interpersonal relationships. Consisting of introductory essays by the editor and a selection of appropriate articles, the book progresses from a definition of humanistic social psychology to discussions of self-actualizing relationships, and relationships between individuals, organizations and society.

480 pages/1973/paperbound \$6.75

BEHAVIOR DISORDERS

Perspectives and Trends/3rd edition

OHMER MILTON and ROBERT G. WAHLER, *University of Tennessee*

The editors have completed a major revision of this outstanding collection of readings. Divided into three sections, The Medical Model, Situational Influences, and Alteration of Behavior, nineteen articles—sixteen new to this edition—provide students with an overview of current thinking and the results of recent psychosocial research on abnormal behavior.

326 pages/1973/paperbound \$5.75

DIMENSIONS OF PSYCHOLOGY

Introductory Readings

Edited by GALE B. BISHOP, *University of Albuquerque*, and WINFRED F. HILL, *Northwestern University*

The editors have selected forty-four articles especially for their capacity to communicate significant research at a level understandable to most college students. The contributors represent a cross-section of researchers, and the selections include material on such relevant topics as drug abuse, mental health and violence.

480 pages/1972/paperbound \$5.95

THE GREAT PSYCHOLOGISTS

3rd edition

ROBERT I. WATSON, *University of New Hampshire*

Professor Watson reviews the lives and works of the principal architects of today's science of psychology from its origins in the thought of pre-Socratic Greeks. Substantially rewritten for added clarity, the book is now available in paperback.

627 pages/1971/paperbound \$6.95

VERBAL LEARNING AND RETENTION

JOHN F. HALL, *Pennsylvania State University*

The author concentrates on providing a comprehensive picture of experimental findings, though pertinent theoretical material is not neglected. Chapters on transfer, retention and forgetting are included, with attention given also to experimental work on short term memory.

590 pages/1971/\$12.95

The Consolidated Roster for Psychology

A NEW LOCATOR-REFERENCE

Published as a Service to the Psychological Community

Compiled from the APA's 1972 Survey of Psychologists in the
United States and Canada

An alphabetized roster of over 45,000 professionals and graduate students, including all APA members and nonmember survey respondents. All levels of training and experience, a full range of employment settings, and all types of positions and specialty areas are represented.

Roster Contents include:

■ Alphabetized Listing

- Name
- Business or Home Address
- Business Telephone Number
- Primary Employment, including Graduate Study
- Two Psychological Specialties
- Highest Degree, Major Specialty Area, Institution and Year
- ABPP or ABPH Diploma Specialty
- State Licensure or Certification as a Psychologist
- Membership in the APA and CPA

■ Geographic Locator Index

United States, Canada and other Foreign Countries, organized by state or province, city, and primary employers. Private Practitioners and ABPP or ABPH diplomates are flagged.

■ Psychology Laws in the United States and Canada

A summarized presentation of the status of licensing and certification of psychologists.

■ Psychological Specialties

A classified reference list of the specialties and codes used in the Roster, including a list of abbreviations.

ORDER your Roster now using the coupon below and enclose your check, payable to the American Psychological Association.

The *American Psychologist* is the official publication of the American Psychological Association and, as such, contains archival documents as well as material submitted by authors. Articles should be timely and of broad general interest to psychologists of all scientific and professional persuasions. Manuscripts must adhere to the instructions on reference citations, preparation of tables and figures, manuscript format, etc., as described in the *Publication Manual of the American Psychological Association*. Manuscripts that do not conform to the style set forth in the *Manual* will be returned for revision. When in doubt about practices of the Journal, authors should examine a recent issue.

Articles under consideration or accepted by another periodical of general circulation are not acceptable. Also, articles accepted for publication by this Journal may not be reprinted elsewhere without APA permission. Comments should be submitted no later than two months from the date of the issue containing an article on which comment is made in order to ensure timeliness. Submit manuscripts in triplicate, accompanied by a 100-120-word abstract, to Kenneth B. Little, American Psychological Association, 1200 Seventeenth Street, N.W., Washington, D.C. 20036.

Statements contained in the *American Psychologist* are the personal views of the author and do not constitute APA policy unless so indicated. APA reserves the right to edit all copy and to refuse ads that are not in consonance with the principles of Title VII of the Civil Rights Act of 1964 (Equal Employment Opportunity).

Written permission must be obtained from the APA for copying or reprinting text of more than 500 words, tables, or figures. Address requests to the Permissions Office.

The American Psychological Association, founded in 1892 and incorporated in 1925, is the major psychological organization in the United States. The purpose of the APA is to advance psychology as a science, and as a means of promoting human welfare. It attempts to accomplish these objectives by holding annual meetings, publishing psychological journals, and working toward improved standards for psychological training and service.

In addition to the *American Psychologist*, the Association publishes 13 other journals: *Contemporary Psychology*, *Developmental Psychology*, *Journal of Abnormal Psychology*, *Journal of Applied Psychology*, *Journal of Comparative and Physiological Psychology*, *Journal of Consulting and Clinical Psychology*, *Journal of Counseling Psychology*, *Journal of Educational Psychology*, *Journal of Experimental Psychology*, *Journal of Personality and Social Psychology*, *Professional Psychology*, *Psychological Bulletin*, and *Psychological Review*. The APA also publishes *Psychological Abstracts*, the *APA Monitor*, a monthly *Employment Bulletin*, the *Biographical Directory*, the *Convention Program*, and the *Catalog of Selected Documents in Psychology*.

Law Enforcement in an Urban Society

J. WOODFORD HOWARD, JR. *Johns Hopkins University*¹

Crime, George Gallup informs us, is the "number one concern" of residents in American cities. Cutting deeply into the freedom and quality of urban life, not to mention private and public purses, crime and fear of crime have come to symbolize a deepening crisis of confidence in American justice and law enforcement. Social scientists, in their capacities as citizens and professionals, have a special responsibility to comprehend this pressing national problem and to decide what can be done about it. At the risk of belaboring the obvious, this article examines four basic conditions affecting the capacity of our legal system, especially of the police and the courts, to cope with urban ills, after which several remedies that are of particular concern to psychologists are suggested.

The Law Explosion

Most social scientists are generally familiar with the range of social problems that we seek to control through law: crime, drugs, welfare, zoning and land use, pollution, family squabbles, economic relations, and so on. Less obvious perhaps is a consequent condition of systemic demand often called the *law explosion* (Jones, 1965). Lawyers invoke this term to convey the enormous growth in both the quantity and qualitative difficulty of contemporary social conflicts to be solved by legal techniques.

The simplest way to describe the explosion is quantitatively. The workload of federal district courts, for example, doubled between 1961 and 1971. Filings in U.S. Courts of Appeals increased over 250% in the last decade. Spiraling caseloads have strained judicial organizations to the point that lawyers speak of crisis, legislatures create new judgeships, and scholars propose new tiers of courts. But the law explosion involves more than volume.

The scope and complexity of legal conflicts have increased no less dramatically than caseloads.

Examine any recent volume of state or federal reports. The cases calling for informed decision range from the legality of the Vietnam war or the Alaska pipeline to the right of rehabilitation in prison or the wisdom of busing schoolchildren. The jobs of "judges and company" are simply harder. Americans increasingly turn to courts to settle social and personal disputes formerly handled by family, church, school, and other branches of government (Gilmore, 1961; Rosenberg, 1971). Behavioral scientists and some judges rightly perceive the need for aid from the social sciences in meeting these demands. Yet professionals on all sides of the bench are at sea about how best to mobilize scientific resources within the framework of the adversary process (Miller, 1968).

The causes of the law explosion are subject to much speculation. Some apparent reasons, for example, population growth, migration, secularization, and urbanization, are worldwide. Some are home-grown. In the United States, as deTocqueville noted years ago, great issues of public policy sooner or later will wind their way into the courts. Americans are also a moralistic people. Our criminal law is a "moral busybody" (Morris, 1973). We have a mental habit that the way to combat a public problem is to throw some federal money and a criminal statute at it. The result is serious overuse of criminal sanctions (Packer, 1968). Even though crime in the United States is primarily a state rather than a national responsibility, the President's Commission on Law Enforcement and the Administration of Justice found in 1967 that federal statutes define over 2,800 crimes. A parallel proliferation of crimes also prevails in most American states (President's Commission, 1967).

Malaise in Criminal Law

Criminal justice and urban problems, to be sure, are not coterminous. Urban law enforcers are taxed by much more than crime. Obviously there

¹ This article is a revised version of a paper presented at a Public Policy Conference for Psychologists, Brookings Institution, Washington, D.C., December 6, 1972.

Requests for reprints should be sent to J. Woodford Howard, Jr., Department of Political Science, Johns Hopkins University, Baltimore, Maryland 21218.

is a growing role for behavioral scientists in such fields as torts, family law, environmental law, hospitalization, and incompetency, to name only a few. Crime is uppermost in the public mind—and for good reason. A recent survey showed that 52% of American urban dwellers feared to walk in their neighborhoods after dark. Last year, one in five Americans and one in three Americans living in central cities considered themselves the victims of crime or attempted crime against their persons or property. No one really knows how much crime there is, nor what causes it. Every discipline offers pet theories; most plausible, none complete. All we can say is that crime exacts a heavy toll in suffering, restricted freedom, and economic loss—and that crime is normal. Every reader at one time or another has been a criminal—or you haven't lived!

Crime is flourishing, far too much. Statistically, as Morris and Hawkins (1970) observed, "the United States may or may not be the land of the free, but it is certainly the home of the brave [p. 57]." Our homicide and assault rates are the highest in the civilized world. It is important, nonetheless, to keep the problem of crime in perspective. Perspective raises the bog of crime statistics, an area of perennial frustration because the best data, the Federal Bureau of Investigation's Uniform Crime Reports, are incomplete, dependent on local reporting and fudging, and seldom adjusted for population growth or inflation. Still, if used cautiously, some lessons come into focus.

1. Americans fear most the crimes that are likely to happen least, that is, violent crimes committed by strangers. The President's Commission reported in 1967 that the risk of serious attack by strangers is two times less than the risks from friends and relatives. Suicide rates are higher than murder rates. So are accidental deaths in homes. People are not necessarily safer on the streets than at home or alone. But the closer the relationship, the greater the hazard.

2. The risk of death and serious bodily harm from the automobile is far higher than from murder and assault. Over 56,000 lives were lost in automobile accidents in 1972, three times the homicide rate. According to the National Safety Council, more than half of all deaths from automobile accidents involved drinking. Yet the slaughter engenders little public alarm and few convictions.

3. It is less well known that, while homicide rates are still rising, murder and robbery rates were sub-

stantially lower (30%) in 1967 than in 1933. Crime rates go up and down with the times.

4. Homicide apart, general crime rates have leveled off and have actually fallen in several large cities such as Washington, D.C., and Baltimore, Maryland. The greatest increases now occur in the suburbs and among women.

The ambivalence of these trends is not to deny the existence of a crisis in criminal justice, but to delimit it. The malaise rises partly from ignorance and fear of the unknown. Too often, misleading crime statistics and press reports alarm the public into hysteria, symptomized by periodic "wars on crime," stampedes on civil liberties and police statistics, political manipulation at budget and election time, and pressures for unsophisticated responses, for example, more police and fancy equipment rather than better training of police and, above all, improved corrections, which everybody generally concedes is the most defective part of the entire criminal process. Even professional police chiefs, such as Patrick V. Murphy in New York and Donald D. Pomerleau in Baltimore, have lamented the uneven distribution of resources throughout the system. What good does it do for police to make more arrests unless the courts and correctional facilities are equipped to handle the increase?

Organizational Fragmentation

American law enforcement, especially in criminal justice, should be thought of as a system of interdependent, though loosely related, parts. Although some people regard the idea of system as more aspiration than reality, a major contribution of the President's Commission on Law Enforcement in 1967 was that, conceptually, it got across the idea that the various agencies of law enforcement are interdependent, rather than separate processes. Like a spider web, change in one element perforce alters the rest. Recognition of interdependence is especially useful in assessing how the strengths and weaknesses of each component affect the others. If we think of the law enforcement mechanism as a system, it becomes clear how fragmented things really are. The central characteristic of American government generally—diffusion and decentralization of institutional authority—is also the central characteristic of the legal structure.

The United States, as Walt Whitman remarked, is "not a nation but a Nation of teeming nations."

Formally, we have 51 legal systems; informally, thousands more. The 1967 census of governments counted 3,049 county governments, 18,051 municipal governments, and 17,107 township governments, most having authority to define and enforce crimes. There are over 25,000 separate police forces in the United States with great variety in organization and practice. The most individualistic decision makers in the country, moreover, are policemen and judges—and I have not forgotten the FBI or the Army Corps of Engineers.

Organizationally, ours is an interdependent system. But the system is one of loosely articulated parts or subsystems: police, detectives, prosecutors, defense counsel, judges, correctional and parole authorities, etc., in thousands of units. This fragmentation, albeit obvious, has several important implications. For one thing, it leads to a "bottom-up" view of the legal process (Dolbeare, 1967). To find the battlefield of urban justice, look down, not up; to state courts, not national; to trial courts, not appellate; to the police above all.

The men in blue talk as if they have the least discretion in the system. In fact they have the most, far more than the prosecutors and judges about whom lawyers fret. *The decision to arrest is the critical nexus of discretion in American law enforcement.* Several studies show that police themselves screen out far more legal infractions from the criminal process than do prosecutors or judges, whom police often condemn for permissiveness (Goldstein, 1960; LaFave, 1965; Morris & Hawkins, 1970).

Whatever relevance these findings have for the presumption of innocence, they speak volumes about the decentralization of authority in our legal order. The overwhelming number of social conflicts never become law suits, the overwhelming number of cases are never litigated in courts, the overwhelming number of litigated cases are never appealed, the overwhelming number of appeals are affirmed at state supreme courts or federal appellate courts, and this holds more for criminal cases than for civil cases. Only for the few cases in which the Supreme Court grants review do exceptions appear to these patterns (Howard, 1974; Jones, 1965). Hence, the overwhelming amount of justice in our system is dispensed in the community not by judges and juries but by the police. On the civil side the same is true of social workers. The police are the key to the quality of urban criminal justice. They have more direct power over the lives of our people

than any other officials. They are clearly the cities' most important social workers, the major representatives of law to the community and, too often, mediators *between* law and the community (Morris & Hawkins, 1970; Reiss, 1971).

One obvious consequence of such decentralized authority is the limited intersection of law and psychiatry. With all respect, the grand debates over criminal responsibility and forensic psychiatry at trial are outside the main current of criminal justice today. Decentralization is also important for understanding police and the problems of their control. Members of each component of the criminal justice system are likely to have different perspectives about their jobs than do those in other parts. Role conflicts abound throughout the system. Such conflicts give rise to a larger theme: the tension between crime control and administrative values, on the one hand, and the values of due process and justice, on the other, flourishing throughout the whole (Packer, 1968).

To illustrate, take the police. The notion that the police automatically arrest everyone who breaks the law, and then turn the offender over to other professionals, is a myth. Police officers perform several jobs, ranging from crime prevention to prosecution, traffic control to social service. They face daily dangers and hostilities in a society deeply ambivalent about authority. All of these functions create an impossible set of expectations. Adding to the burden is extreme personal discretion. For unlike other professionals, police usually exercise their discretion alone, often without direct supervision in hostile environments, and with only post hoc standards of performance (Wilson, 1968).

What guides police discretion? Patrolmen tend to have a different view of their role than do other actors in the system. Their model of the job is not so much law enforcement as maintaining order, a task in which enforcing law is merely one of several means that may have to be ignored. By contrast, other actors in the system espouse a law enforcement view of the policeman's job. That is true of lawyers and judges, even detectives and professional police managers, and certainly it is true of their educated, middle-class constituencies. Thus, the police tend to have a peacekeeping view of their job implying wide discretion, while their constituencies tend toward a law enforcement view implying limited discretion. As James Q. Wilson (1968) showed, police chiefs are often the key

figures because they set the style or model to be followed in each community.

This divergence in role conceptions underlies much of the conflict between levels of a diffused legal system, especially over standards of evaluating performance. It also conditions police responses to external controls. The fact is that we have different standards of evaluating police behavior. To patrolmen, the norms of law enforcement, which may lead a professional police chief to go "by the book" or a judge to probate, are *conflict creating*. And so to a ghetto dweller, the middle-class professional norm of law enforcement comes over as harassment, because the law is unevenly enforced and everybody knows it. Wilson's (1968) description of changing police styles in Oakland provides an instructive example. After a new chief shifted the emphasis from peacekeeping to law enforcement, "all hell broke loose."

Of course, similar conflicts occur among officials in courts and corrections. Tension between the two models—crime control versus law enforcement and due process—exists throughout the legal system. We hear much talk today about law and order, as if the two always go together. In fact they do not. It is an ancient insight that law and order, not to speak of justice, may collide. Today the collision locates most directly in the daily work of the police.

Any seasoned bureaucrat understands that role conflicts of this sort are endemic in government. Administrative decentralization, however, makes the task of applying intelligent controls much more difficult. Fragmented organization means that few formal mechanisms exist to coordinate or resolve conflicts among the system's component parts. The major controls are *internal* within each subsystem. As Reiss (1971) pointed out, that is important not merely because it converts the courts into supervisors of police and prison officials, but because procedural rather than substantive issues tend to dominate our methods of control. Each subsystem also tends to create informal bureaucratic protections and shortcuts, much of it "justice without trial." Bargaining among prosecutors and defense counsel over guilty pleas is one prominent example. Passing the buck of determining criminal responsibility from jurors to psychiatrists as expert witnesses is another.

The most vexing products of diffused organization are our difficulties in controlling police misconduct. Basically, there are three principal con-

trol mechanisms over the police: (a) political-administrative, (b) judicial, and (c) professional. Presumably, it is the job of political authority to put Humpty-Dumpty together again, as in Britain or France, where ministries of justice coordinate and supervise the activity of the police, the courts, corrections, etc. However, the evidence strongly suggests that supervision by political authority in this country is fragmented, spasmodic, and particularistic. Mayors, governors, or attorney generals may occasionally issue orders to get tough on speeders, go easy on blacks, or clear the streets of addicts and prostitutes, but there is no common policy-making authority among the parts. Nor do the parts devise or monitor policy cooperatively. For all the efforts of the Law Enforcement Assistance Administration to encourage states and municipalities to create planning councils for criminal justice, these organs are usually little more than advisory groups or interdepartmental coordinating committees.

Consequently, the police and the courts are often in conflict, each attempting to control the other laterally, the police through the decision to arrest, the prosecutor through the decision to indict, and the courts through the control of evidence. Though police officials do not operate in a total policy vacuum, they clearly operate more independently in fact than in theory. How otherwise can we explain the diversity of what is called an arrest in this country or the divergent policies governing police interrogation prior to *Miranda v. Arizona* (1966:384 U.S. 436)? In most instances, our constitutions, statutes, and responsible political authorities gave no clear standards to guide interrogation of suspects. Police departments tended to make those policies themselves. The outcomes ranged as widely as the systematic exploitation of the psychology of confessions, condemned in *Miranda*, to the FBI's anticipation of *Miranda* itself.

Inadequate administrative supervision of police led to the second form of control, judicial review. Yet judicial controls are inherently limited. Lacking direct organizational command, judges wield mainly the sanctions of excluding evidence from trials and reversing convictions. At best these are indirect, lateral controls which put a premium on procedure and encourage a vicious cycle of continuing appeals. The irony is that, whatever one thinks of decisions like *Miranda*, the effects on police are probably exaggerated (Becker, 1969).

Judicial attempts to supervise police also produce a curious interplay with the third or internal control, professionalism. The Supreme Court resorted to the exclusionary rule and legislated the rules as to warnings during interrogation because the justices lost faith in police discipline. These rules contrast markedly with those in Britain and other English-speaking countries where illegal evidence is admissible in court if considered trustworthy, while police are disciplined administratively for obtaining it illegally. As Benjamin Cardozo asked years ago, Why should the criminal go free because the constable blundered? At the same time, however, the Supreme Court has relied on the professionalism of patrolmen on the beat in approving authority to "stop and frisk" (*Terry v. Ohio*, 1968:392 U.S. 1). And the Court's remedy for in-custody questioning is the countervailing professionalism of its own kind—lawyers—with differing professional values and orientations. How effective is professionalization—internalized standards as distinct from external political or judicial controls—over police conduct? To my mind this is one of the vital issues underlying the whole controversy between the courts and the police. The New Left and the Old Right appear to unite in the belief that government institutions, including law enforcement agencies, are overloaded in resolving social tensions. Doctors, lawyers, and professors all claim the right as professionals to supervise themselves. Can we safely entrust the same to the police?

Overload of the Courts

A symptom of the law explosion amid organizational diffusion is a quantitative overload of judicial machinery in many cities which seriously strains the quality of urban justice. First is interminable delay in civil cases, especially in state courts (Jones, 1965; Zeisel, Kalven, & Buchholz, 1959). Though some trial courts have cleared their dockets by crash programs, an average delay of two years in civil cases is not uncommon. The automobile is the chief culprit. So-called accidents inflict not only their statistically predictable quotient of death and injury, but also the injustices that inevitably arise between weak and strong litigants under the law's delays (Ross, 1970).

A second result of overload is assembly-line processing in urban courts, especially criminal courts. Even excluding traffic cases, one study in Los Angeles a decade ago estimated that the average

workload per judge was 2,500-4,500 cases per month. The average trial time was 1½ minutes. It was estimated then that a 5% increase in not-guilty pleas would paralyze the courts—a prediction which the Watts riot confirmed. Los Angeles is not atypical. It is shocking but true that "the great mass of criminal cases, divorce proceedings, and adjudications into mental illness, alcoholism, narcotics addiction, and juvenile delinquency" are disposed of on "an assembly-line basis" all over the United States (Jones, 1965). This is volume processing by mass production techniques, not adjudication as studied in school. Furthermore, these are the very problems with which most citizens confront the courts, the most intractable of human problems we attempt to solve through law, and, all too frequently, the locus of discrimination among "haves" and "have nots" (Jacob, 1969, 1973).

A third manifestation of overload is "justice without trial." Together, delay and workload have spawned an informal system of pretrial bargaining and settlement so pervasive that our system may well have changed under our noses from a system of adversary adjudication to a process of decision predominantly pretrial in character (Skolnick, 1966). Adjudication in court no longer defines our system. Adjudication is largely a consequence of failure to settle by negotiation or by threat. That is true of both civil and criminal cases. In the great cities, trial has become "a painful last alternative" in private actions (Jones, 1965). In criminal cases, too, a wide range of practices from prosecutor screening and plea bargaining to assembly-line trials reduce criminal trials to a fraction. Though cities differ widely in their methods of weeding out cases, most resort to one form or another of mass processing to avert adjudication (Jacob, 1973; McIntyre & Lippman, 1970).

The most worrisome of these techniques is plea bargaining. Guilty pleas have become an administrative imperative in keeping the American trial courts open. In 1969, over 95% of the felony cases in New York City and 80% of those in Philadelphia were disposed of by guilty pleas. In U.S. district courts, too, guilty pleas account for roughly 90% of all convictions. Now, much is to be said for the practical advantages in pretrial bargaining. Defendants usually receive lesser penalties than they would after trial in a system in which sentences are, generally speaking, excessive. Justice is swifter and cheaper than by trial and can be flexibly tailored to individuals (Jones, 1965).

Adjudication in court has always rested on preliminary screening and argument to narrow the scope of conflict (Fuller, 1964). Plea bargaining fits within a broad trend toward pretrial settlement among fully informed parties in accordance with the values of voluntarism and privacy.

Let no one mistake the risks, however. Foremost is regression to a presumption of guilt. A negotiated plea presupposes guilt. How is that guilt determined? The answer is administratively without the procedural safeguards that the adversary system, for all its faults, promotes. The law explosion aggravates the danger because prosecutors, defense counsel, and judges share a common interest in expediting the volume. Cooptation of erstwhile adversaries at the expense of individual defendants is a constant temptation (Skolnick, 1966).

Thus, plea bargaining intensifies the tension between administrative and due-process values in the criminal process. Most defendants will and *must* plead guilty or the judicial process in many American cities will collapse. This is what underlies police resentment of the Warren Court's extraordinary moves enlarging the right to counsel and governing police interrogation—not the loss of a few individual cases, but the impact on scarce time and resources in contexts of massive volume pressures, threats to public order, and declining public confidence in the thin blue line. And it helps to explain why compliance with these decisions has been equivocal (Becker, 1969; Oaks, 1970).

A book could be written about the ramifications of court overload, but two conclusions bear emphasis. First, the problem of striking a balance between individual rights and social needs in this field will not yield to ideological flack, Left or Right, but only to hardheaded decisions rooted in the realization of what our system has become. Second, overload, itself a symptom of an urban society, may not have reached the point of crisis; but mushrooming intakes, along with the other conditions described, impose serious constraints on the capacity of judicial institutions to control urban conflicts, let alone to direct social change in lieu of stalemated political agencies. I stress these limits not to replay Cassandra's theme, nor to underrate the contributions of courts to social reform, but to warn against the easy assumption that the judiciary offers a substitute around a blocked or overloaded political process. Personally, I think that courts have responded to urban problems as

well if not better than the rest of the government. But they are too limited structurally, functionally, and physically to provide a safe haven from the old cliché that our governmental system, like a piston engine, works best when all the parts work in concert. That is another way of saying that the judiciary offers no escape from the tough, collective political tasks lying before us in legislatures and executive agencies. In short, the law enforcement apparatus alone cannot solve the problems of crime in America.

Remedies

What then can be done? A responsible critic should stress that there are realistic reforms and proximate solutions that would substantially improve the capacity of law enforcers to deal with urban problems. It is symptomatic of the malaise that most of these proposals have flourished among experts for at least two generations. While no single line of attack will accomplish much by itself, in concert the following general approaches would help considerably in making law enforcement more effective.

MORE RESOURCES

Though increased spending is the bureaucrat's eternal remedy, the case is strong that until quite recently law enforcement has been underfinanced. As late as 1969, the total expenditure for law enforcement at all levels of government was \$6.7 billion, roughly equivalent to the space program at its peak (*Baltimore Sun*, May 4, 1972; Committee for Economic Development, 1972). Former Chief Justice Warren has put the point graphically: The annual budget of the federal courts equals the cost of one cruiser. Despite the recent spurt in federal spending for law enforcement, the police, the courts, and especially corrections remain badly overtaxed.

REORGANIZATION

It follows from the fragmentation of authority that substantial reorganization is in order to improve controls and coordination among the interdependent parts of the legal system. The classic argument of Benjamin N. Cardozo in favor of ministries of justice at local levels is still to be refuted—or acted upon. Surely it is possible to devise ways in which political authorities and judges could sit

down with police chiefs, prosecutors, defense counsel, public defenders, and correctional officials to improve the administration of justice without undermining the adversary process in individual cases.

Similarly, heavy reliance on pretrial stages of litigation creates an urgent need to stiffen procedural safeguards during plea bargaining. Many dangers in this practice would be reduced if controlled by the elementary standards of due process (e.g., notice, the right to counsel, a public hearing) which courts and legislatures require for other forms of administrative adjudication and which police demand for their own disciplinary proceedings. Another promising approach is to relieve the courts from settling disputes that other agencies are better equipped to handle. A prime example is automobile accidents. No-fault insurance would remove the single greatest cause of delay in court and provide superior compensation to accident victims at lower cost (Bombaugh, 1971). Mediation and arbitration offer still further alternatives to adjudication in court (Rosenberg, 1971).

REORIENTATION AND REDISTRIBUTION OF RESOURCES

For once, however, the usual bureaucratic remedies of more personnel, more money, and reorganization are not enough. A consensus is emerging that Americans need to reorient their priorities and to redistribute their resources in order to combat crime more effectively (National Advisory Commission on Criminal Justice Standards and Goals, 1973). At the top of the agenda is a more realistic, less moralistic, and less ambitious conception of the criminal law. John Stuart Mill urged over a century ago in *On Liberty* that society is justified in depriving an individual of life or liberty only for its own self-protection, not for the purposes of reforming the immoral. While the aims of the criminal law are multiple, the central object is protection of persons and property (cf. Hart, 1958; Morris & Hawkins, 1970). Government should get out of the business of enforcing private morals by changing the substantive rules that make criminal law a "moral busybody." Legislatures in Britain, Illinois, and New York have successfully completed this task and, in response to the recommendations of the Brown Commission, recodification now proceeds in Congress.

A few examples will illustrate why the case for *decriminalization* is so compelling. Over half of American arrests concern crimes without victims.

The crime of being drunk in public accounts for almost one third of all arrests (President's Commission, 1967). Granted, rounding up drunks and bums consumes a smaller portion of police time and represents informal relief to alcoholics and derelicts. But the "revolving door" is obviously defective as a social welfare policy and represents a serious diversion of police resources from the prime task of public safety. For example, only six drunkards in the District of Columbia were responsible for 1,400 arrests and combined sentences of 125 years at a public cost of \$600,000 (Morris, 1973).

Other so-called "victimless" crimes, such as vice, gambling, pornography, and sexual deviation among consenting adults, generate similar exercises in futility. The criminal process is an ineffective and inappropriate way to control these eternal, yet intensely personal, transgressions. For lack of complaints, police discretion is greatest in these fields. Organized crime, temptation to corruption, and entrapment of informers abound. Police cannot possibly enforce all of these laws evenhandedly. Prosecution is a lottery (LaFave, 1965; Newman, 1966). Over two thirds of those arrested for gambling are blacks. Such conditions put law enforcers in an untenable position, erosive of public confidence. For as Reiss (1971) observed: "Selective enforcement of unpopular laws invariably is seen as the arbitrary exercise of authority [p. 176]."

Alcoholism and drug abuse are among modern society's most unyielding scourges. The ineffectiveness of criminal sanctions to control them suggests the superiority of the British approach of treating both conditions as essentially medical problems. Though hardly a panacea, this approach at least reduces the incentives to criminality and the threats to public safety now involved in supporting these habits as well as the breeding grounds of organized crime and corruption. Accordingly, many authorities support measures to decriminalize personal possession and use of drugs in reasonable quantities and to make access relatively easy under medical supervision, while imposing strict controls over supply (Morris & Hawkins, 1970). By like token, we should get tough on dangerous *behavior* such as drunken driving, as in Sweden; on possession and use of "Saturday Night Specials," which are far more dangerous to friend and family than to strangers; and on tempters, such as drug pushers.

Thus, decriminalization by no means embodies permissiveness or removes these social problems from legal control (Morris, 1973). Still less does decriminalization imply that criminal sanctions are inherently futile. On the contrary, while the deterring effects of criminal penalties are poorly understood and debatable, the Internal Revenue Service has demonstrated the potency of selective prosecution as a deterrent in taxation; and recent research supports the old notion that certain punishment is a stronger deterrent to crime than severe penalties (Wilson, 1973). Rather, the priority of public safety simply means that we need to be more discriminating in the use of criminal sanctions. Americans have long cheapened the concept of crime by overuse and underenforcement (Hart, 1958; Packer, 1968).

In tandem with decriminalization should go redistribution of resources currently being expended for law enforcement. The prime targets should be the police and corrections. We ask of the police decisional competence and responsibility comparing to the greatest of our professions, yet pay them a pittance after giving them inferior training. One of the saddest statistics in the President's Commission report of 1967 was that the average training time of police in cities with a population under 250,000 was less than three weeks. Hence, we should support efforts to professionalize the police, knowing full well that there will be unanticipated consequences, such as increased unionism and involvement in municipal politics to define the rules affecting police. At the same time, the police should be removed from nonessential functions like directing traffic, which the Danes found women perform better than men and with greater civility.

Corrections are commonly viewed as the chief failure of American criminal justice. High recidivism rates and prison uprisings have eroded public faith in the rehabilitative ideal. While reform of the human animal has never been an object to inspire much optimism, there is no reason to retreat from the goal of correction as long as we recognize its limitations. Rehabilitation is not the only aim of the criminal law, nor has it always failed. What fails are assumptions that the only fit punishment for crime is jail on a massive scale. Over 1.3 million convicts are now in the correctional process at an annual cost of over \$1.5 billion dollars. One can support a student in an Ivy League college annually for the cost of maintaining an inmate in prison. Bail reform alone promises

to save many millions of dollars now spent on feeding and housing prisoners in overcrowded jails. Over half of the local jail population merely await trial. Many will not be convicted. No attempt is made at corrections. If anything, incarceration amounts to little more than cram courses in crime.

It is small wonder that rehabilitation appears to be such a failure. Seldom has it been seriously tried. Despite some suggestions in the literature that the end result is the same no matter the type of institution, controlled experiments here and abroad, especially by the California Youth Authority, suggest a governing principle that the more we rely on family, group, and community ties the greater the chances of success (Morris & Hawkins, 1970). This principle, embodied in the American Law Institute's proposed Model Penal Code, means that social isolation should be the last resort rather than the first. Imprisonment should be limited to what is necessary for public protection and corrections. For those who do not constitute a threat to others or themselves, we should aim at swifter, more certain punishments, such as restitution, that avoid social ostracism. For those who must be detained, the rhetoric of rehabilitation should be taken seriously by programs, above all in smaller institutions, that stress education, job training, and counseling along with gradual reintroduction into community life via work release programs, furloughs, and halfway houses, practices similar to those now fashionable in the field of mental health. No illusions should be harbored about the outcome or about public support of community-based reforms. Still, more humane ways hold promise as cheaper and more effective methods of meeting what Chief Justice Burger called our "collective moral responsibility" to help the nation's half-million prisoners become more productive members of American society (*Baltimore Sun*, December 8, 1971).

Finally, redirection of priorities and resources also should be on the agenda of psychologists and psychiatrists. As an outsider whose knowledge is at best secondhand, I state this conclusion humbly. But the impression is hard to escape that scientists of the mind do not play major roles in the processes of criminal justice. Strained relations among lawyers and behavioral scientists, of course, are neither new nor surprising when we consider that their concepts and methods "share about the same degree of ideological kinship as does the Mafia and the

Women's Christian Temperance Union . . . [Allen, Ferster, & Rubin, 1968, p. ix]."

However, part of the difficulty lies in the direction of psychiatric energies. Forensic psychiatry has focused primarily on problems of trial, for example, perception and evidence or the insanity defense, highlighting the irrationality of the legal model of rational man. These are important, fascinating issues in which morals, science, and law connect. Yet, from a systemic standpoint, psychiatric efforts seem misdirected and marginal. For trials, as we have seen, are but the tip of the iceberg. And trials, as Karl Menninger and others have long argued, do not center on the critical, unsolved problems of how to identify potentially dangerous offenders and how to treat those who are psychologically disturbed (Menninger, 1968; Morris & Hawkins, 1970). These are the jugular questions on which progressive programs of pretrial and postconviction release depend.

A strong case exists for shifting the emphasis of behavioral scientists away from trial and toward pretrial and posttrial stages of the criminal process, where the action is. For psychiatrists, this means less emphasis on diagnosis and more emphasis on treatment. One need not banish psychiatrists from the courtroom to see merit in proposals to abolish the insanity defense as a distraction that breeds discrimination among defendants and only marginally defines the pathological basis of crime (Halleck, 1966; Morris & Hawkins, 1970). Resources thus saved could be far better spent during sentencing and in postconviction treatment of mentally disabled criminals (Lindman & McIntyre, 1961).

Morris and Hawkins (1970) also made an appealing recommendation that, given the frequency of guilty pleas and the failures of detention, psychologists should place top priority on research to identify socially dangerous offenders. Every official from patrolman to parole officer must make such predictions now. Cooptation of psychiatrists and psychologists as adversaries at trial has shaken confidence in the relevance of individual case histories and clinical insights to those judgments. What we need, in conjunction with clinical analysis, are statistical profiles and probability tables, based on experience in various types of crime, of potentially dangerous defendants so that responsible authorities can weigh the risks of release before and after sentencing. However these proposals for aggregate data may jar clinical traditions, neither

judges nor the public are likely to accept community-based release programs without harder evidence than they now receive of the risks to public safety. Peeping Toms, for instance, seldom have courage to commit serious sex offenses. How much effort has been expended in predicting more dangerous forms of criminal conduct than the relatively insignificant threat of potential skyjackers?

For law-related disciplines, as for courts and police, the conclusion is thus the same. We need a more discriminating allocation of tasks and resources among the various elements of the legal process, pending fundamental attacks on what we presume, without really knowing, are the two chief causes of urban crime: the lack of social justice in cities and conditions in American prisons. Reasonable men will differ about these suggested remedies, most of which have been around for years, but *something can be done*. The nub of the problem is less imagination than will.

Harm, Offense, and Nuisance

Some First Steps in the Establishment of an Ethics of Treatment

DANIEL N. ROBINSON *Georgetown University*¹

In a recent article (Robinson, 1973) I attempted to outline certain tensions and contradictions between current (and imminent) psychological therapies and principles of constitutional law. The purpose of the earlier article was to encourage analysis of the problem, and, out of a desire not to foreclose the necessary debate, I avoided presenting any specific recommendations. This gave the article a certain hit-and-run flavor which I hope to repair in the present article.

Because the domain of *ethical practices* is a vast one, it is important at the outset to establish the limits of the present discourse: I am concerned here only with the principles that guide therapeutic efforts directed at individuals who either have not consented to be treated or who, by virtue of their state or condition, are not in a position to engage in those rational operations required for a meaningful and valid consent. This is not to say that what follows does not apply to voluntary therapeutic associations, only that it does not *necessarily* apply. In further delimiting the sphere of concern, the present article takes as *given* that some degree of coercion is inescapable in a free society, that no right is absolute, that the State has legitimate interests which it is duty bound to hold in trust for the people, and that these interests can and do conflict with the will of individuals. A brief but remarkably complete evaluation of these as "givens" is offered by Feinberg (1973). I will depend heavily on his development of the grounds for coercion in the following section.

¹ I wish to acknowledge the critical reading of this manuscript by H. Arkes, M. Beauchamp, T. Beauchamp, J. Cortes, N. Finkel, J. Notterman, and R. Ruskin.

Requests for reprints should be sent to Daniel N. Robinson, Department of Psychology, Georgetown University, Washington, D.C. 20007.

The Ethics of Coercion

Feinberg (1973, p. 33) summarized traditional justifications for coercion under seven principles:

1. *Private harm.* In this instance, the State (or, really, any agent) may justifiably limit the freedom of an individual when the failure to do so will cause real harm to that individual, for example, the forcible prevention of suicide.

2. *Public harm.* Here, the individual is justifiably restrained from actions that will harm those institutions of governance in which all the people have a just interest. Forcible prevention of the disclosure of State secrets in time of war would come under this rubric.

3. *Legal paternalism.* This principle is rooted in the conviction that the State has a just interest in each of its citizens and may (must) therefore prevent them from doing injury to themselves. This is logically tied to Principles 1 and 2.

4. *Offense.* Unlike John Stuart Mill, who insisted that society need only remain "aloof" from those who offend it, those who support the offense principle insist that society has the right to legislate against actions that offend the sensibilities of the larger community, for example, laws against public lewdness.

5. *Legal moralism.* There are cogent arguments which insist that the notion of civilized society is an empty one unless it is granted that certain moral precepts are common to its members. To this extent, the State may justly prevent actions that ignore or defy moral convention. To remove this principle from that puritanical context for which modern society has such little patience, I offer the torture of animals as an example of the application of legal moralism. The torture of animals involves no harm to human beings; it offends no one if practiced privately. Yet, it is judged to be un-

conscionable by the public and it is outlawed by the State.

6. *Extreme paternalism.* This principle was most fully articulated by Plato in *Laws and Republic*. According to it, the State must guide the moral development of its citizens, must save them from the corruptions that are intrinsic to the masses. It is based on the belief that the public at large lacks the discipline, motivation, and talent necessary to protect its own interests, even to *learn* its own interests. Arguments for a philosophizing, for a benign dictator, for the State as suprapublic all rest on this principle.

7. *Welfare.* This is the other side of Principle 6. According to it, the public is to reveal its wants and the State is to operate in such a way as to "optimize" this public good. This principle is the cornerstone of utilitarian ethics.

None of these justifications for coercion is devoid of merit nor is it necessary that any one of them exclude the others in attempts to justify actions against the freedoms of an individual. A policeman may prevent a man from jumping from a window because such an action will harm the individual (Principle 1), because it is in violation of the laws of the State and therefore threatens the authority of its legal institutions (Principle 2), because he is sworn to protect life (Principle 3), because he—the policeman—finds the act personally offensive (Principle 4), because the law judges suicide to be immoral (Principle 5), because the man at the window does not know what is good for him (Principle 6), and/or because the State is charged with the task of securing a happy and prosperous life for each of its citizens (Principle 7).

It is one thing to assert that each of these justifications enjoys some merit but quite another to suggest that they are all equally valid. And it is manifestly the case that they do not share equally in the force of law. Yet, while not sharing *equally*, they have all, on one occasion or another, been relied on to validate a legal judgment. Important decisions in free-speech cases point this out convincingly. In the landmark case of *Schenck v. United States*,² Justice Holmes, speaking for a unanimous Court, delivered the now-famous "clear and present danger" criterion. While it reversed a lower court's conviction, the *Schenck* decision clearly removed free speech from the category of

absolute right. Indeed, in *Whitney v. California*,³ Justice Sanford, in delivering the opinion of the Court, removed all doubt: "The freedom of speech which is secured by the Constitution does not confer an absolute right to speak, without responsibility, whatever one may choose."

In *Schenck* and in *Whitney* (the Court affirming the convictions in both of these cases), the relevant issue was that of clear and present danger, whether the spoken or written material constituted a threat to the public order, to the safety of citizens, or to the security of the United States. But over the years, the Court has broadened the contexts in which free speech might be legitimately suppressed and has even included "symbolic" speech, as in the case of *United States v. O'Brien*⁴ where the burning of draft cards was judged to be unprotected by the First Amendment. Presenting the decision of the Court, Chief Justice Warren offered these portentous words:

A government regulation is sufficiently justified if it is within the constitutional power of the government; if it furthers an important or substantial governmental interest; if the governmental interest is unrelated to the suppression of free expression, and if the incidental restriction on alleged First Amendment freedom is no greater than is essential to the furtherance of that interest.

From *Schenck* and *Whitney* to *O'Brien*, there has been a subtle but continuous liberalization of the restraints on the individual states in their regulation of speech. In some respects, the midpoint of this development is found in *Beauharnais v. Illinois*,⁵ in which the Court upheld the right of Illinois to prevent the distribution of racist pamphlets and to prosecute those responsible for such distribution. While avoiding the question of clear and present danger and relying instead on the fact that the pamphlets were libelous, the Court acknowledged the connection between the *offense* and *public harm* principles; that is, certain expressions of free speech were so *offensive* as to be conducive to civil strife. Indeed, while settling the matter on the basis of libel rather than clear and present danger, the Court, through Justice Frankfurter, insisted that "no one would contend that obscene speech, for example, may be punished only upon a showing of such circumstances." (The "such circumstances" being clear and present danger.)

² *Whitney v. California*, 247 U.S. 357, 47 S.Ct. 641, 7 L.Ed. 1095 (1927).

⁴ *United States v. O'Brien*, 391 U.S. 367, 88 S.Ct. 1673, 20 L.Ed. 2nd 672 (1968).

⁵ *Beauharnais v. Illinois*, 343 U.S. 250, 72 S.Ct. 725, 96 L.Ed. 919 (1952).

² *Schenck v. United States*, 249 U.S., 47 S.Ct. 247, 63 (1919).

Implications

I cite several of these First Amendment cases not only because they involve what are generally recognized as our least violable rights but because they describe the gradual transfer of legitimacy from *harm principle* justifications to *offense principle* justifications, and this transfer must have implications for those engaged in rendering therapy to involuntary patients. The clearest implication is this: If the State is now less restrained in abridging certain forms of expression, it is, perhaps, commensurately freer in assigning those found guilty of illegal forms of expression to therapeutic contexts. I insert the "perhaps" because the Court has yet to establish the boundaries of therapeutic intervention. There are, however, three decisions that would appear to bear heavily on any future judgments the Court may make in this area and it is profitable to review them. Each centers either on the Fifth Amendment's protection against self-incrimination or the Fourteenth Amendment's guarantee of due process, or both. (Over the years some Justices have interpreted the Fourteenth Amendment as but a shorthand form of the first eight amendments; others have proffered upon it a unique set of protections.)

The Case of Gerald Gault

Gerald Gault* was a 15-year-old boy who had been placed in a detention home pursuant to a neighbor's complaint that he had been making obscene telephone calls to her. Committed as a juvenile delinquent (i.e., on noncriminal charges), Gerald was ordered to spend six years in the home; the time required for him to become legally responsible. Under criminal statute, had Gerald been 18 the penalty would have been no more than two months in jail and a fine not exceeding \$50.

I need not go into the myriad bases on which the Supreme Court overturned the ruling of the juvenile court. Gerald and his parents had been denied nearly every element of legal consideration entailed in the concept of due process. It is sufficient for the present purpose to examine part of the decision as read by Justice Fortas:

A boy is charged with misconduct. The boy is committed to an institution where he may be restrained of liberty for years. It is of no constitutional consequence—and of limited practical meaning—that the institution to which he

is committed is called an Industrial School. The fact of the matter is that, however euphemistic the title, a "receiving home" or an "industrial school" for juveniles is an institution of confinement. . . . Under our Constitution, the condition of being a boy does not justify a kangaroo court. . . . Against the application to juveniles of the right to silence, it is argued that juvenile proceedings are "civil" and not "criminal" . . . [but] . . . the availability of the privilege does not turn on the type of proceeding . . . but upon the nature of the statement or admission and the exposure it invites.

Justice Fortas then addressed himself to the assertion that Gerald Gault had been consigned to a home and not a prison:

Proceedings to determine "delinquency," which may lead to commitment to a state institution, must be regarded as "criminal" for purposes of the privilege against self-incrimination.

Concurring with the majority, Justice Black added this:

Where a person, *infant or adult*, can be seized by the state to be confined for six years, I think the Constitution requires that he be tried in accordance with all the guarantees of all the Bill of Rights . . . [italics added].

If we substitute "mentally ill" or "psychologically disturbed" or "antisocial" or "infirm" for "boy" and "juvenile," we gain some sense of where the Court stands on several aspects of psychological therapies. It would seem, for example, to follow necessarily from the decision in *In re Gault* that the fact that someone is not being "tried" on "criminal" charges for purposes of "imprisonment" has nothing to do with his rights against self-incrimination and of due process. If the possible outcome of the enterprise in which he is involved is involuntary incarceration in any place "*however euphemistic the title*," he cannot be compelled or tricked or confused into testifying against himself. Whether psychological tests ordered by a court fall into this domain remains to be decided, as does the status of expert testimony when based on information volunteered by an individual during psychological or psychiatric interviews. In this matter of self-incrimination, the two following cases are of moment.

Rochin v. California

Mr. Rochin⁷ was suspected by the police of selling drugs. One morning, the police entered his quarters without warrant or appraisal and found him sitting with his wife. On a table next to the bed were two

* *In re Gault*, 387 U.S. 1, 87 S.Ct. 1428, 18 L.Ed. 2d 527 (1967).

⁷ *Rochin v. California*, 342 U.S. 165, 72 S.Ct. 205, 96 L.Ed. 183 (1952).

pills which Rochin grabbed and swallowed before the police could intervene. Unable to force the pills out of Rochin, the police rushed him to the hospital and ordered an attending physician to administer a gastric lavage. One product of this medical procedure was the two pills which, on subsequent analysis, were found to be morphine.

The Court reversed the previous conviction of Rochin and in concurring with the opinion as put forth by Justice Frankfurter, Justice Black added these words:

[A] person is compelled to be a witness against himself not only when he is compelled to testify, but also when as here, incriminating evidence is forcibly taken from him by a contrivance of modern science.

However, that the matter is far from settled is evidenced in the more recent (1966) decision in *Schmerber v. California*.⁸ In this case, a conviction was gained against Schmerber as a result of an analysis of his blood following an automobile accident. Speaking for the majority, Justice Brennan refused to overturn this conviction, in part, because "the test chosen . . . was a reasonable one . . . and performed in a reasonable manner." In this case, where the brutality of the *Rochin* case is not present, the State's rights in criminal matters are held higher than the individual's. In regard to *Schmerber*, the test followed the ascertainment of "probable cause" (i.e., there was an accident involving reckless and, therefore, perhaps, *drunken* driving), and this was therefore not in violation of protections against unlawful searches and seizures. Perplexingly, the majority did not find that the extraction of blood constituted the involuntary according of self-incriminating testimony.

From the foregoing, it would seem that (a) rather broad discretionary rights are available to the State in obtaining the kind of evidence necessary for convictions when this evidence is of a non-verbal variety—this may well include the evidence implicit in psychological tests and (even) interviews where the latter lead to interpretations of "illness" rather than proof of criminal intent or action—but that (b) the overall process involved in obtaining this evidence is protected constitutionally even though criminal prosecution is not involved, that is, even if the gravest consequence is (involuntary) hospitalization.

Because it is clear from the foregoing that the rights of the patient may not be as faithfully or

fully protected as the given therapist would wish, it is necessary to explore what is *right* (ethically) and not just *legal* (adjudicatively). This exploration brings us back to the principles of coercion borrowed from Feinberg (1973).

Therapeutic Intervention and the Principle of Private Harm

Society does not derive its right to prevent harm to itself or its members from the necessities of logic but from the necessities of civilization. One need not subscribe to the rigorous *legal* and *moral paternalism* of Plato's Spartan model of the State to accept the right of a majority to live under law, unmolested by their neighbors, and protected against the villainies perpetrated by the ignorant and the diseased. Even Rousseau (1960), who was as far from the idea of Spartan order as Western philosophers have been wont to move, treated some actions as those of "a rebel and a traitor to his country" who, when imprisoned or put to death, suffers "as an enemy rather than a citizen . . . and, in such a case, the right of war involves the killing of the vanquished [p. 200]." Quite simply, the *sine qua non* of that condition of life we call "civilized" is the rule of law over the rule of passion. It would seem, therefore, that individuals presented for treatment—for therapy, behavior modification, etc.—for reasons of having physically harmed others can lay no moral claim on the right not to be changed. Whatever evidence is marshaled legally by the state preliminary to their "sentencing" is evidence, *prima facie*, that just cause for therapy exists. It is my view (and here I answer to the criticism that my earlier article was insufficiently proscriptive) that proof of physical harm, intentionally perpetrated on one's self or on another, constitutes a forfeiture of what, earlier, I called "the right to be different" (Robinson, 1973). This, however, is limited to private harm.⁹

Therapeutic Intervention and the Principle of Public Harm

Public harm, while potentially more injurious to more people, presents a different case for the therapist. We are no longer dealing with a person who

⁸ *Schmerber v. California*, 384 U.S. 757, 86 S.Ct. 1826, 16 L.Ed., 2nd 908 (1966).

⁹ I employ *private harm* in the rigorous sense of acts now proscribed by laws against homicide and suicide. Thus, the alcoholic or the smoker, who might do himself personal harm, is readily excluded.

physically jeopardizes his own life or that of another. Rather, he conspires, through speech, gesture, and seditious conduct, to undermine the institutions of governance. His actions are against the State, are politically motivated, and, while perhaps "deluded," are not necessarily "crimes of passion." The duly constituted authorities may have every good and legal right to arrest this person and to imprison him. Indeed, those who, during World Wars I and II, were in sympathy with Germany, who conspired to steal secrets of state, and who attempted to dissuade young men from enlisting or serving in the armed forces were arrested and were imprisoned under laws deriving their force from the principle of public harm. But suppose the psychological disciplines had effective therapeutic methods by which the political convictions of these individuals could be transformed. Suppose it had been possible, through drugs, surgery, or conditioning, to cause them to desist from seditious and treasonous actions. Would the application of these methods, even if *legal*, be *right*? I submit that such applications would not be right and that the domain of treatment and healing is in no way connected by allegiance to any particular State in which it may be temporarily located or exercised. The domain of treatment and healing exists for the benefit of those who voluntarily solicit its remedies and not for the benefit of any particular ideology, no matter how congenial that ideology might be to the goals of the therapist. Indeed, even in the instance of the private harm principle, compulsory therapy is offered as an "evil" of lesser gravity than the ultimate evil of death or life in prison. It is in this sense that the therapist strives to save the individual from the worst act the state may execute against him, and it balances a reluctance to intervene against the harm the individual might *personally* do to others.

Therapeutic Intervention and the Remaining Principles of Coercion

Since I have drawn the line separating warranted and unwarranted therapeutic intervention just under the principle of private harm, it necessarily follows that intervention for "offense" and for "nuisance" is proscribed. Society, through its laws and its immense power of persuasion, would seem to have all the influence it needs to spare itself the embarrassments of "offensive" actions and the inconveniences promoted by public "nuisances." The individual who would rather be treated for his

homosexuality, alcoholism, exhibitionism, etc., than imprisoned for these "compulsions," should be given the option. But in instances of victimless crime, there would seem to be no ethical or principled basis on which the therapist must foist his treatments on an unwilling patient. That examples can be culled from the vast region of possibility which show that involuntary therapy would be better than a therapeutic laissez-faire is merely to prove that life in a free society is seldom ideal. In instances of victimless crime or of crimes that involve merely an offense to sensibility, the Court has held that the State may arrest and punish the perpetrators. But, to state it still another way, every punishable act does not constitute a justification for involuntary therapy. Transferring moral paternalism from the legislature to the counseling room (or surgical theater) can have only monstrous consequences. It is in this connection that we must distinguish between the paternalism exercised in the behalf of children and that which treats adults as if they were children.

The State requires that children receive some fixed number of years of formal education to prepare them for the responsibilities of citizenship. Children are required to be educated not because they are "sick" and because knowledge is "therapeutic" but because they are uninformed. Indeed, physicians are also required to receive education for licensure and this is not because they are "sick." Therapy, no matter how we debate it on theoretical grounds, is legally distinguishable from education, and adults are similarly distinguishable from children. The illiterate child cannot participate in a meaningful way in representative government; he cannot comprehend those details of political action that bear upon his rights and opportunities. The inveterate homosexual, however, may be a model citizen; he may be intelligent, hard working, politically conscientious. That his conduct is "maladaptive," that society may chastise him, or that the police might arrest him are possibilities he must weigh. If, according to the view of some, he is "sick," they have every right to offer him their evidence, as does the Surgeon General in the matter of tobacco. Whether and how he chooses to act upon this advice is for him to decide, even if his decision leads to imprisonment. Laws and conventions are more easily changed than is one's personality once effectively treated by the arsenal of therapeutic modalities. For the therapist who is unwilling to draw the line at the private harm principle, for the therapist who is willing to

treat those involuntarily assigned to him on the basis of offensiveness or because they are "nuisances," for this therapist the pool of potential patients is large and varied.

If Illinois can prosecute Beauharnais for the lamentable villifications contained in his pamphlet, an Illinois judge can well decide that Beauharnais needs "help" and many would concur. But aspersions just as libelous and tawdry were shouted and written by extreme student radicals throughout the 1960s and were directed at *specific* groups also. In the last analysis, is the therapist's unwillingness to reform the behavior of the involuntary patient to be based on the sympathy that *particular* therapist has for the *particular* libels, slanders, and degradations heaped on some isolated group by that *particular* "patient"? *Mein Kampf* was authored in a prison cell and there are few who do not rue the day it found its way to the printer's press. Many would now submit that *any* therapeutic procedure would be justified in keeping such ideas from the public domain. But if this is the popular will, it can be expressed in *law*. Behavioral and medical scientists have no role in arbitrating the competing claims between individuals and society in general. Our charge is to inform, not to transform, our fellow citizens unless they seek such help with the full knowledge of the consequences attend-

ing their receiving it.¹⁰ Since the popular will can change the laws but not the therapies, protections against the latter must be drawn more sharply. Until the courts get around to doing it, practitioners must exercise informed restraint. At the present time, this restraint should begin with the refusal to administer compulsory therapy in all cases not embraced by the principle of *private harm*. Even in those instances in which private harm is involved, there are limits to the nature and extent of involuntary therapeutic intervention. These, at least provisionally, are best established by balancing the potential harms of treatment against the real damages contained in the Court's sentence.

¹⁰ I recognize the enormity of the issue of consent. In this article I have evaded it by stipulation, that is, by discussing only those instances in which the patient validly withholds consent or in which his consent is suspect.

Controversy Concerning the Criminal Justice System and Its Implications for the Role of Mental Health Workers

DAVID E. SILBER *Institute of Criminology, Hebrew University of Jerusalem*¹

The old debate over how to view criminal offenders, always lively and occasionally acrimonious, has taken a new turn in the past decade or so. The argument used to be over whether criminals were sick (and thus ought to be treated instead of punished) or bad. The new dimension is concerned with the consequences of a psychiatric conception: (a) Is it an encroachment of civil liberties? and (b) Is the treatment conception psychologically sound? The issues are complicated and interlocked, emotionally charged, and important to society. Before going to the question of treatment and roles for treatment workers, it would be worthwhile to review the arguments; what follows is an attempt to separate the main hypotheses of both camps.

Criminal Behavior Is Symptomatic of Psychological Disturbance

This was the enlightened liberal position. Many psychiatric writers (Abrahamsen, 1967; Alexander & Healy, 1935; Alexander & Staub, 1956; Halleck, 1967; and Lindner, 1946; among others) have characterized criminals as having the same traumatic developmental difficulties, leading to similar deficient personalities, as neurotic individuals. Often the explanations hypothesize the same psychosexual connections between adult criminal behavior and infantile fixations as are assumed to operate in the formation of neurotic behaviors: "We direct our regard back to the fog-enshrouded days of infancy and early childhood, when were laid down the irrevocable patterns of our lives [Lindner, 1946, p. 58]." The most passionate advocate of the psychoanalytic-psychodynamic in-

terpretation of criminals as "mentally ill" is probably Menninger (1968). Menninger argued that society's response to criminals (as evil and immoral persons) is as misguided as earlier notions that mental illness is a sign of satanic possession.

Most interpretations of criminal behavior as disturbed are made in a reformist spirit, usually coupled with appeals to radically change the criminal justice system. Proposals usually include changing the court system, changing the role of mental health worker, and transforming the prison system: "We [the public] commit the crime of damning some of our fellow citizens with the label 'criminal' and having done this, we force them through an experience that is soul searing and dehumanizing [Menninger, 1968, p. 9]." Their alternative proposals may be summarized as follows:

1. *Precriminal detection.* Delinquency-prone youths should be detected prior to contact with the police, to allow preventative measures (unspecified) to be instituted. Presumably this might entail enforced treatment for uncooperative juveniles and/or their families.

2. *The substitution, in most cases, of informal nonadversary proceedings (either civil or criminal) for the formal adversary proceedings now characteristic of criminal trials.* Others (e.g., Glueck, 1962) have argued for some informal method of determining guilt or innocence that would not take *mens rea* ("evil intent") into account, in much the same way that juvenile court is supposed to work.

3. *The substitution of indefinite sentences² for fixed or indeterminate sentences.* Along with an

¹ Requests for reprints should be sent to David E. Silber, Department of Psychology, George Washington University, Washington, D.C. 20006.

² The indefinite sentence lasts until the person is pronounced "cured," as in the case of civil commitments to a mental hospital. The indeterminate sentence is a penalty sentence, usually with a maximum and minimum time specified.

indefinite sentence, the person would be remanded to a treatment center rather than to prison for incarceration. Institutionalization would be mandatory, but the aim would be correction of psychological disturbance and social rehabilitation.

4. *Treatment.* Psychotherapy in one form or another would be widely used, along with environmental manipulation, guidance, and education. It is recognized that some persons might have to remain in such confinement programs on a more or less permanent basis. Interestingly, most commentators do not mention using the newer behavior modification techniques in their proposals for such treatment centers, although psychologists in prison settings often do (Brodsky, 1972).

In short, the general purpose of these proposals would be to provide settings where the man, rather than the deed, is adjudicated and treated.

The New Opposition

To a growing body of civil libertarians, these proposals are appalling and pose a challenge to personal freedom occasioned by the growth of what they call the "Therapeutic State." Kittrie (1971) has admirably clarified the threats to traditional legal safeguards posed by nonadversary civil commitment proceedings. Szasz (1963) has attacked the intrusion of psychiatric thought into the legal arena as a curtailment of liberty. Treatment in specialized corrective facilities and mental hospitals has been attacked by Spece (1972) on the same grounds. In the process, the concept of the mental health worker as a helper of persons takes a dreadful beating. We come off, instead, as wanting a piece of the legal action (Christie, 1971), ill-informed and judgmental (Szasz, 1963), sloppy in thought and hasty in action (Kittrie, 1971), or unreflective and mildly sadistic (Spece, 1972). It would be wise to take close heed of the main points raised by these writers.

1. Informal, civil proceedings jeopardize a person's basic rights ordinarily guaranteed under criminal law. Such rights include the right to counsel, specified indictment, time to prepare a defense, trial by jury, be present during the proceedings, confront adversary witnesses directly, and be judged solely on the basis of innocence or guilt.

2. Civil commitment for indefinite periods is a judgment against the person, not the deed, and as such represents a step toward totalitarian social control. Indefinite sentences also unfairly penalize

the person accused of crimes which normally carry light sentences.

3. Once committed, a person loses all civil liberties and is even more vulnerable to enforced treatment and mistreatment than the incarcerated prisoners.

4. Psychiatry and clinical psychology contain inconsistent, contradictory views of human functioning, so that any psychiatric stance in a legal proceeding is capable (in good faith) of being opposed by another psychiatric stance.

5. Treatment programs are widely carried out without theoretical rationale, or solid empirical support. Little is known concerning the relative efficacy of various treatment programs, if, indeed, they even work. An especially problematic area is physical intrusion into the body as a way of changing behavior, such as occurs with electroconvulsive shock treatment, electrical stimulation of the brain, injections of noxious substances during aversive conditioning, and psychosurgery of one kind or another.

6. "Mental health" concepts, as uncritically applied to convicted persons, are not based on medical considerations, but rather on social and ethical value systems.

7. Coercive treatment programs stand little chance of success precisely because they are coercive.

8. Psychiatrically oriented institutionalized treatment programs extant have failed dismally, yet are "total institutions," as are prisons, and are often even more degrading and dehumanizing than prisons. The social stigma of the label *mentally ill* is at least as bad and enduring as being labeled *criminal*.

These objections leave unsolved the problem of what to do with and for the convicted offender so as to provide correctional rather than retributive experiences during imprisonment. And they completely ignore the question of whether the individual criminal is in a position to perceive what is best for himself.

An indirect result of these arguments, however, is that they make it appear that treatment and therapy are the order of the day in correctional facilities. Professionals and the general public alike tend to believe, as does Antilla (1972), that "treatment ideology has achieved a kind of breakthrough within the last few decades [p. 287]." Bazelon (1972) has criticized psychologists for failing to change the majority of offenders, after making the explicit assumption that "the experts—

you—are minding the store [p. 151].” This is not a fair attack because it is not true. Mental health workers in the adult correctional system are few and far between, and treatment is the exception, rather than the rule. The rest of this article will examine what ought to be the role of the mental health worker in the criminal justice system, what activities might be expanded, and what avenues for staffing might prove fruitful.

Roles for Mental Health Workers in the Criminal Justice System

In view of the foregoing, it is quite clear that mental health workers in the criminal justice system must examine and question what their role ought to be. This section proposes limits and reiterates some areas where increased efforts and programs can be developed.

First, mental health workers should become very leery about testifying in court. Almost all writers, including Menninger, have complained about psychiatric testimony, yet psychologists and psychiatrists continue to march to the witness box with increasing frequency. Interestingly, the pressure may come more from the prosecution than the defense. Kittrie (1971) quoted a study done in the criminal courts of the District of Columbia which found this to be the case. In such instances, where psychiatric workers are directed to testify, reports ought to be limited to the current mental status of the defendant. If the defendant is suspected of being acutely psychotic (and thus unable to participate in his own defense), the determination ought to follow from a formal civil commitment procedure. In other situations, the mental health worker ought to avoid doing what he patently cannot: that is, render a post hoc judgment of psychological status. Since the major grounds of exculpation are now via the M’Naughton rule, evidence in support of it should come from people who observed the defendant at the time of the offense. To qualify as a defense under M’Naughton, a person would have to be so overtly psychotic as to appear so even to untrained observers. Another reason for allowing adjudication to follow from legal considerations has been stressed by Rubin (1965): Treatment can be as meaningful and successful in a prison facility as a mental hospital or special treatment program. Mental hospitals have the wrong “set” for treating felons; they perceive the patient as helpless and disturbed. Most criminals are not out of contact with reality, but rather are deviant in social values and behaviors.

Similarly, mental health workers ought to invoke extreme caution before suggesting mandatory treatment programs as substitutes for imprisonment. Removal from society is punishment, and mandatory treatment programs, with indefinite commitments, constitute potentially greater punishment to the individual than determinate imprisonment. Even the fact that such treatment programs would be controlled by the state health or social welfare agency is a questionable advantage, because abuses to patients could more easily masquerade as “treatment” and elude legal detection. An example of the dangers to civil liberty is the project outlined in the American Psychological Association *Monitor* of August 1972 (“Treatment Camps for Addicts”). The plan would call for mandatory treatment of addicts in special camps, in order to protect society from drug-occasioned crime and speed the addict’s “recovery.” There was no mention of how the incorrigible addict would be identified or adjudicated, what legal safeguards would be present during or after commitment proceedings, or what treatment modalities would be used. It is clear from the article that the recalcitrant or negative inmate would face long-term confinement indistinguishable from a prison setting except for the lack of an expiration date.

Research into effective methods of treatment ought to be encouraged, but the research personnel should be drawn from staff outside of the correctional setting. The mental health worker in the correctional institution ought to function as an ethical watchdog to discourage dangerous programs. There are enough innocuous techniques available which have not received adequate scrutiny so that such methods as, for example, aversive conditioning using anectine (Spece, 1972), can be eschewed for a very long time.

Finally, in deciding where the role of the mental health worker ought to be, it can be argued that prisons are not necessarily any more static than other institutions of society. In addition, correctional programs have the practical advantages of being already in existence, having avowedly rehabilitative goals, and having (in most states) a central coordinating office. In general, the mental health worker ought to stay out of the adjudication process and in the correctional system.³

³ There is a valuable service that mental health workers can render without infringing civil liberties: to protest against laws which define psychologically abnormal or unusual behavior as criminal, for example, laws against homosexual behavior between consenting adults.

Treatment in Correctional Settings

Most prisoners receive little or no systematic treatment of any kind. Even in the Lewisburg Federal Penitentiary, this has been found to be so (Rother & Ervin, 1971). There seems to be three major reasons for this: First, the staffs of most correctional facilities are woefully inadequate. In 1967, it was estimated that the ratio of professional staff to prisoners was 1:179 nationally (Task Force on Corrections, 1967). Smith (1971) quoted a survey that listed only 60 full-time psychiatrists for 230 adult correctional facilities in the United States. Clearly, the experts are not "minding the store."

Second, most prisoners do not manifest "traditional" forms of psychopathology. Using data quoted by Brodsky and Vandiver (Brodsky, 1972), Smith (1971), plus Brodsky's survey (1970), it is clear that the percentage of psychotic and neurotic individuals is quite low (ranges of 1%-3% and 4%-7%, respectively). The major diagnostic category was some variation of the character disorder/psychopathic personality label. Such prisoners are hostile, suspicious, and immature and tend to identify with subcultural values that are legally proscribed. They usually perceive their personality functioning to be acceptable. They are not, in general, likely to clamor for individual psychotherapy and usually are seen on referral. Thus, there is no strong sustained interest on the part of prisoners themselves for treatment.⁴

Finally, the custodial staffs of prisons usually view the professional staff with ambivalence or outright hostility. They worry about the possibility of riots, believe that prisoners are generally incorrigible, and suspect that therapy is a form of mollycoddling. Guards usually have little or no formal training in psychology or human relations, often fear and dislike the prisoners they are charged with guarding, and may resent the professional because of his higher status. They therefore are often reluctant to encourage the expansion or initiation of treatment programs within the correctional setting and may passively oppose ones already present.

Thus, it is one of life's little ironies that treatment is attacked because it does not help prisoners (Antilla, 1972; Bazelon, 1972), when in fact the prisoner's chance of receiving treatment is almost zero. Therapy has not been given the chance to

work, and it ought to have that chance before being written off as worthless. Treatment has been identified with psychoanalytically oriented individual psychotherapy, an error that has gone largely unchallenged; obviously, there are more and newer techniques in use. Let me now suggest some specifics concerning treatment in corrections.

THE DIAGNOSTIC AND RECEPTION CENTER

Increasingly, prisoners are being sent first to these centers. To have an impact on the prison career of the inmate, diagnosis and classification should occur as soon as the offender is incarcerated. The same panoply of professionals as in a well-run mental hospital should have contact with the prisoner, and the results should be discussed at a case conference. Major decisions concerning diagnosis, therapy, and placement with the system would be made there, and a particular "package" tailored to the individual would be arrived at. The inmate should be given feedback; diagnosis is too often a one-way street. This is a particular danger in corrections, where hostility and suspicion are excessively present anyhow. The center staff ought to use the feedback technique to motivate the prisoner to get involved in his own rehabilitation. Enough general evidence exists to conclude that if a prisoner is treated as a dignified and reasonable human being, he will more often than not respond in a like manner. A similar procedure has been in operation in North Carolina, which seems to offer some sort of crisis intervention aid, such as found in a neighborhood community mental health center, for prisoners with acute disturbances.

THE TRADITIONAL PRISON SETTING

Within the penitentiary and reformatory, the mental health worker can be a treatment source and "system challenger" (Brodsky, 1972). As a system challenger, he ought to goad the administration to eliminate retrogressive and abusive regulations; as a positive contribution, he should intervene to work on the attitudes and behaviors of the custodial staff toward the offender. Such activities would include in-service training for current staff, human relations instructions to new guards, role-playing sessions, and psychological instruction. To explicate the viewpoint implied above: The mental health worker stands outside the institutional hierarchy. I would argue that the first concern of the therapist is the client, and by staying on the periphery the mental health worker can make his

⁴ The opposite view is that prisoners recognize the low quality of treatment services and stay away for that reason (American Friends Service Committee, 1971).

contribution most effectively. This is neither "radical" nor antiestablishment, but simply the recognition that treatment works best when the therapist is not identified as a cog of the system by the inmate. Thus, activities such as sitting on disciplinary boards, writing parole recommendations, or acting as an information conduit to the administration are not properly within the treatment worker's purview.

The backbone of the mental health worker's activities ought to be as a purveyor of therapeutic services. The immediate questions that arise are, What sort of therapy and with whom? Usual guidelines applied to nonincarcerated patients are meaningless, given the behaviors and personality configurations of prisoners. Practical considerations dictate that the cheapest and most intensive methods be used most often, such as group therapy, behavioral techniques, and marathon therapy groups. The few published reports available suggest that intensive therapy can be effective (Sindhu, 1970), as can therapeutic community organization (Miles, 1969), marathon-type retreats (Carroll & McCormick, 1970), and behavior techniques and token economies (DeRisi, 1971; Wright, 1968). Experience suggests that intensive, Synanon-type marathon groups are particularly effective when embedded in the context of regular group sessions.

Simply reducing defenses or eliminating undesirable attitudes and symptoms is not enough, considering the environment to which the prisoner usually returns. Treatment legitimately includes teaching the prisoner ways of putting the institutions of society to work for him (a point suggested by Warden R. Williams, 1970, of the Maryland House of Corrections) and ways to either change or avoid negative environmental influences.

Ideally, the report of the diagnostic center will accompany the prisoner, so treatment—if desirable—can start immediately. If, however, we really take seriously the issue of individual civil rights, prisoners should not be coerced directly or indirectly into participating. Thoughtful explanations of method and desirability are indicated, especially in instances where noxious stimuli or stress methods are used (e.g., in Synanon-type encounters).

Mental health workers can serve as informal counselors to self-help groups such as Alcoholics Anonymous or the Black Muslims. Ethnic-pride groups such as the Black Muslims can have a profound effect on prisoners, and mental health workers should feel free to offer aid. There are two other activities that the treatment worker should do,

but probably will not be allowed to do: (a) arrange human relations seminars between inmates and guards, and (b) arrange couples groups in the prison which include both inmates and their spouses (or fiancées).

PARTIAL-RELEASE AND POSTRELEASE SETTINGS

The need to confront the social realities and pressures on ex-offenders in their readjustment to street life marks the partial-release and postrelease efforts as perhaps the most important correctional and treatment settings. Two important innovations in the recent past have been the halfway house (usually in an urban setting) for nondangerous offenders and the work-release program (usually operated out of an honor camp). Counseling, and especially experientially oriented group therapy, can be crucial here in alleviating the great strain placed on someone who is *in* a free environment, but not *of* it. The therapist will have to handle complaints and frustrations, help control impulsiveness, defuse defenses, and serve as a stable model—all without appearing smug or saintly. Immediate family members can be brought into the treatment at this point, in combined family groups.

Currently there are almost no programs of post-release treatment. This is extraordinarily unfortunate, as the first postrelease year is apparently the hardest; something on the order of 40% are rearrested within the first year (Federal Bureau of Investigation, 1970). Aftercare programs run by the correctional system should be quickly established, so that treatment can either be continued or be available if needed. I stress the need for these to be under the aegis of the correctional system because its professionals are probably most qualified to perceive the special problems of ex-offenders in making a satisfactory postrelease adjustment.

All of the foregoing makes no sense at all, given the current staff situation in the correctional system. In addition, it is no secret that many are incompletely trained or marking time until something better comes along. Recruitment is hampered because salaries are relatively low (Task Force on Corrections, 1967), prestige is low, and prisons are frequently away from the urban scene, where professionals like to locate. There are, however, a number of pragmatic, relatively inexpensive remedies available. Perhaps the single most neglected resource is the university-based professional training program. All programs in clinical psychology, social work, and psychiatry require significant

amounts of field experience. There is no reason why correctional facilities cannot function as training centers (as, for example, does Jackson State Prison in Michigan). State universities in particular ought to be approached, given their common funding source. To give the correctional-system professional more status as a supervisor, those who meet licensing requirements could be appointed as adjunct clinical staff (a current practice for hospital staff supervisors). An even more innovative plan is in practice in North Carolina, where mental hospital psychologists are hired by the University of North Carolina itself, then assigned to field placements in hospitals and clinics. Something like this could be done with correctional staff as well, thus providing them with perceived prestige, as well as resolving some staffing problems.

A second possibility is for departments of corrections to underwrite the cost of professional education in return for a commitment to work for a number of years following graduation. This system seems to work for the armed forces and the Veteran's Administration, many of whose career professionals were recruited that way. Within the system itself, employment would be more attractive if the duties of the mental health worker were split between various institutions. Or, if not practical, some sort of biyearly rotation between institutions could be offered. Finally, professionals could be enticed by the offer of five-fourths pay; that is, they would be allowed to take one full day per week for outside consulting while receiving full pay and benefits.

Interrupting the cycle of arrest, conviction, and rearrest is crucial; as New York City Police Commissioner Murphy (1972) said, the correctional systems must be changed and changed rapidly. Offering full mental health services at every stage of the prison experience—from sentencing to and after release—can help achieve this goal while offering satisfying roles for mental health professionals within the criminal justice system.

Reflections on Introspection

JOHN RADFORD *North East London Polytechnic, England*¹

Joynson (1970, 1972) has argued for the use of introspection in opposition to what he regards as the "generally accepted doctrine" (Broadbent, 1961) of objective experiment. This view "defines the subject matter of psychology as behaviour rather than mental life; it rejects the view that psychology investigates conscious experience through introspection [Joynson, 1972, p. 1]." Now this view, as Joynson allowed, has perhaps never been "generally" accepted, though it has been extremely influential. As an example of a phenomenon that ought to interest psychologists, but that might have no behavioral counterpart, C. A. Mace used to give an *unfulfilled intention*: "He thought of going out by one door, but actually went out of another." Mace (1965) observed that "psychology is regaining consciousness [p. 1]." Burt (1962, 1968) put a forceful case for the study of consciousness.

On the other hand, some writers, imbued with the "accepted doctrine," have gone to considerable lengths to incorporate some of the phenomena of consciousness within a respectable behaviorist framework. Hebb (1968) presented a somewhat tortuous argument with respect to mental imagery. He wished to "dispose of what seems to be a misconception, that reporting imagery, or describing it, is necessarily introspective [p. 466]." His argument is, first of all, that experiences may give rise to reactions: experiences, that is, in the sense of stimulus conditions that can be specified by an observer. Among the reactions may be vocal sounds or indeed verbal reports. But these are simply objectively recordable instances of behavior: "It is obvious that in such reactivity—when I burn my fingers and say 'Ouch'—no question of looking inward arises. My verbal response is no more de-

pendent on introspection than a dog's yelp when his tail is trod on [p. 467]." The processes involved can, in principle, be reduced to a physiological chain of cause and effect. In the case of imagery, much the same chain is called into play, except that the initial stimulus is absent. To make his point, Hebb (1968) quoted the case of a *phantom limb*: Above the level of the amputation the same nervous mechanisms may operate as before the limb was lost. The same argument applies to *memory imagery*:

Though there is now no sensory input, the same central process, more or less, is exciting the same motor response—more or less. . . . It is the same outward-looking mechanism that is operative, not introspection. . . . At least, it is not introspection in the sense of a special inward-looking mechanism of self-knowledge [p. 467].

This led Hebb to suggest that "the mechanism of imagery is an aberrant mechanism of exteroception." This is an odd view, for why should imagery be in any sense "aberrant"? Imagery is presumably a form of internal representation of the environment, and there is no reason to think such mechanisms anything other than natural. The view arises, however, from Hebb's determination to abide by what he regards as "the rules of objective psychology, in which mental processes are examined by inference, and not by direct observation [p. 468]." This is interesting, for Hebb seems here to adopt the exact opposite of the view of the classical introspectionists. "One does not perceive one's perceptions," said Hebb, "nor describe them; one describes the object that is perceived, from which one may draw inferences about the nature of the perceptual process [p. 467]." Now this view of perception itself can certainly be questioned. Piaget and Inhelder (1966), for example, held that even when one makes a copy of a drawing, it is not the drawing that is copied directly, but a mediating image of the drawing. However, even if the mechanism of perception were of a stimulus-response kind and even if the mechanism of imagery were similar, it would not follow that the reporting of the image was not introspective. It

¹ This article is based on a section in *Thinking: Its Nature and Development*, to be published by John Wiley in 1974.

might not be systematic, as in some of the classical studies (I suspect this is part of what Hebb meant by a "special" mechanism). And, of course, the *statements* about the image can be treated as behavior. But that is not the same thing as saying that no introspection is involved, as I hope to show.

Let me quote another attempt to bring some of these awkward phenomena within the behaviorist fold. Bourne, Ekstrand, and Dominowski (1971) presented a textbook, *The Psychology of Thinking*. But thinking must be treated in a certain way: "Thinking is purely and simply a behaviour concept . . . thinking is a simple noncommittal way to describe a behaviour which, like all behaviour, is completely observable [p. 7]." With this view, it is not surprising that introspection finds no place in the book, nor indeed that "thinking" is restricted to concepts, problems, and language. This view is interesting, because it is almost identical, in essence, with that of J. B. Watson. The latter, as is well known, wished to reduce thinking to subvocal language, that is, a particular aspect of observable behavior. It might be felt that in 50 years little has changed. All the behaviorists we have quoted have been happy to include speech in their objective studies, and Boring (1953) suggested that this meant that introspection was being allowed to carry on its business under a new name, that of *verbal reports*. But this, it seems to me, is unfair to the behaviorists.

It seems to me that we can distinguish between introspections as data and introspection as a method. By "data" I mean here the statements of introspections, not the objects of introspection. Introspections as data in this sense can, I think, always be treated as verbal reports, if that is what we wish to do. They can be recorded in the same way that we record "the subject pressed the lever," or "the subject scored x on the test." What is recorded is "the subject says that . . ." he has an image, a feeling, etc. Such records must, of course, be subject to the usual checks used for all experimental data and in particular must yield satisfactory levels of significance. It may also be argued that records of this type need a special sort of check, analogous to that used for personality questionnaire responses. Essentially, this is not to take the response at its face value, but to establish empirically its relationship to some other variable. This might be an aspect of the stimulus con-

ditions, and/or other behavior.² Some examples are provided by Woodworth (1938). If this can be done then, it may be argued, statements of introspections can be considered acceptable in the same sense as other widely accepted sorts of psychological data.

But is there, in fact, no difference between Hebb saying "Ouch" and a dog yelping? The real issue must lie in whether there is another class of data, distinguished by being accessible only by a particular method, that of introspection. This question has a number of aspects. Philosophically, it is a version of the body-mind problem. Historically in the behavioral sciences, there has been the change from regarding consciousness as a reservoir of experience to be investigated directly, to regarding it as a construct, inferred from other observations (Boring, 1953). As we noted, that is Hebb's view. But there are also more strictly psychological aspects.

The first of these is that "the method of introspection" covers several different, though related, methods. McKellar (1962) offered a classification of these. He made six sorts of distinctions:

We may first contrast the systematic methods of "classical introspection" with those of a relatively unsystematic kind. Secondly, the use of trained introspectionists differs from the work of the Gestalt psychologists and others who sought, by introspection, to study the phenomena of naive human experience. Thirdly, introspections may be classified by the circumstances in which they are obtained: the laboratory, the clinic, the analytic situation, and daily life. Fourthly, some introspection is carried out mainly for communication to the experimenter, while in other cases it is carried out partly or largely to extend the investigator's own empathic understanding. Fifthly, introspection under normal circumstances may be contrasted with the use of the method in special, experimentally produced circumstances: those produced by drugs, sensory deprivation, hypnosis, etc. Sixthly, we may contrast introspections made or elicited by trained psychologists from those made or elicited by others [p. 628].

This is the only classification of introspective methods I have come across in the recent literature. Clearly, McKellar's distinctions do exist, though perhaps they are not all of equal theoretical importance. For example, introspections when the subject is or is not under the influence of a drug would not appear to be different *methods*, though the *results* will very likely be different in the two cases—as would the results of any observation. It seems to me, considering the range of activities that have been referred to as "introspection," that three groups can be distinguished, in terms of what it is

² I owe this point to E. Valentine.

that the subject is to do. There are, first, cases of self-observation. The individual reports on his own experience: He aims to observe his own mental events, in the same way that an astronomer observes stars or a behaviorist observes responses. Second, there are self-reports: By this I mean cases in which the person tells of his experiences, but without trying to be objective—for example, experiences under unusual conditions. Third, there are cases of thinking aloud: the technique used, for example, in Duncker's (1945) well-known experiments on problem solving. These distinctions are not absolutely clear-cut, but they do, I think, refer to three different activities. Wundt distinguished between introspection and self-perception (Boring, 1953). By the latter I take it he meant what I have called self-reports. For introspection proper, trained observers were required. The distinctions are confused by several factors. First, all the activities can, in principle, be more or less systematic. That is to say, the experimenter (who may also be the observer) can exercise a greater or less degree of selection. This feature, however, has in practice been an issue mainly in the first case. Watt (1904; quoted by Humphrey, 1963) developed the method of fractionation in an attempt to get at thought processes by systematic self-observation. Second, the activities have in use sometimes been confounded. A good example here is psychoanalysis. The only point about the analytic use of introspection that is clear is that it comes at the extreme end of the nonselective range, because the prime rule for the patient is to hold nothing back. Now there is a sense in which psychoanalysis could be said to use what I have called thinking aloud: The patient simply says out loud what is passing through his head. He does not have to observe himself; that is the analyst's job. In this respect psychoanalysis takes on a curiously behavioristic air, for the analyst deals with what is objectively observable: the patient's behavior and speech. (A patient might make a remark and add: "I meant . . ."; and the analyst might reply: "Let us look, not at what you meant, but at what you said.") Since the rule is to hold nothing back, however, the patient will inevitably also engage in self-observation. And since the aim of analysis is to give the patient more control over his own behavior, he will, if the analysis is successful, become more objective about what he says (and does). He moves, in a sense, from being subject to being experimenter. The analyst *also* makes inferences about the patient's internal experiences,

and the patient learns to do this too. A third confusing factor, though of less importance here, is that it is difficult to be sure that introspection is not always in fact retrospection (Bakan, 1954).

It will be seen that the data resulting from all three methods can, if desired, be treated as verbal behavior, in the way we have already discussed. A further step can be taken, and mental events can be inferred from this behavior. The first method, however, that of introspection proper, is distinguished in that its essential aim is to make direct observations of a particular class—observations of events not otherwise accessible. The distinction between these and other events is expressed by Bakan (1954) as that between experience and that of which the experience is. It is brought out by the example of the *stimulus error*. The phrase was coined by Titchener (Boring, 1957) to refer to the "error" of an observer in lapsing from the psychological viewpoint, in reporting on phenomena, to some other viewpoint. The psychologist should report on what he experiences. It is for the physicist, or some other scientist, to report on the external stimuli that bring about the experience. Boring instances a two-point threshold: The Titchenerian psychologist's task was to report when he experienced the two points as one, regardless of the fact that he knew there were two.

This brings out another aspect: the question of trustworthiness. As Boring (1953) pointed out, in classical psychophysics controls are not used; the control lies in the training of the subject. Psychophysical experiments can, of course, be done with animals using methods of discrimination training. Titchener ruled out of psychology animals (and children and clinical patients) because they could not be trained to observe their mental events and to distinguish between these and physical events.

Thus, it seems important to know whether there is a unique method; and if so, whether this should be used by psychologists, either among other methods or, as Titchener demanded, exclusively. Classical German psychology, as established by Wundt, defined psychology as the science of experience: immediate experience, not inner experience, because there is no valid distinction between inner and outer experience. As Boring (1957) put it: "The data of experience are merely themselves; a perception does not have to be perceived in order to be a perception; it has only to occur [p. 332]." This is interesting in view of Hebb's objection to introspection, quoted earlier. However, it follows from this definition that the method of psychology is

that of self-observation. For Wundt, "having an experience is the same as observing it [Boring, 1957, p. 332]." Boring spoke with great authority, yet a glance at the simplest form of Wundtian experiment casts doubt on this. For example, Wundt (1924) himself gave as an introductory and basic experiment listening to a metronome and observing the way in which we perceive the beats falling into a rhythmic pattern. The attempt to be more systematic led the followers of Wundt, notably Külpe and Titchener, to emphasize the training necessary for such self-observation.

A number of departures from, and reactions against, these views took place in psychology. They include Gestalt psychology and psychoanalysis. The most extreme, as far as method is concerned, was behaviorism. It was on this point that Watson took his stand. He wrote in 1930:

Behaviourism, as I tried to develop it in my lectures in Columbia in 1912 and in my earliest writings, was an attempt to do one thing—to apply to the experimental study of man the same kind of procedure and the same language of description that many research men had found useful for so many years in the study of animals lower than man [p. IX].

Watson seems to have had several reasons for this view. One was his interest in the study of animal behavior itself. Another appears to have been an intense dislike of any suggestion of mysticism, such as he felt was involved in the study of consciousness. The only point of theoretical interest, however, is that of objectivity. Watson (1930) equated behaviorism with objective psychology, and introspective psychology, with subjectivity. He does not, however, present any arguments in support of this.

Thus, Watson agreed with the classical psychologists in insisting on a particular method, necessitated by a particular subject matter. Some attempts have been made, on the other hand, to resolve the opposition. Thus, Boring (1953) argued:

Operational logic, in my opinion, now fuses this single dichotomy because it shows that human consciousness is an inferred construct, a concept as inferential as any of the other psychologists realities, and that literally immediate observation, the introspection that cannot lie, does not exist. All observation is a process that takes some time and is subject to error in the course of its occurrence [p. 187].

But the dichotomy is not fused here, for if consciousness is inferred, it presumably cannot be observed directly. Thus, Boring comes down on the side of the physicist and not the (Titchenerian)

psychologist. It is, besides, not satisfactory to reject a method merely because it can lie. Infallibility of method does not exist in science.

A more sophisticated attempt is due to Burt (1962). He argued that the early objection to introspection, that two observers would disagree, was merely the result of failing to realize the importance of individual differences. The behaviorist insistence that data be public is unhelpful, because certainty in science is unobtainable. This objection, argued Burt, rests on the distinction between what is "public" and what is "private." Thus, it is said that language is inadequate to convey the experience of one person to another. But, in general, we do understand what is meant. Then it is said that only one person can observe the events of consciousness. But strictly speaking, this applies to every firsthand observation. The behaviorist attempt to make introspections respectable by treating them as verbal reports merely misdirects our attention, for it is precisely the subject's experience, not his verbal behavior, in which we are interested. Burt next argued that the model of the physical sciences adopted by Watson was a crude and oversimplified one, which would not be accepted now. It is not clear, however, what in Burt's view would be accepted; nor whether he thinks this presumably more sophisticated model appropriate for psychology. Finally, Burt attacked the newer behaviorists' argument from the principle of parsimony. A system such as that of Hull, Burt claimed, is far from parsimonious. And parsimony can only be achieved, in any case, when a science has reached a highly developed stage. Here again Burt's arguments are open to objection. Given that behaviorism is not parsimonious, it could still be more so than introspection. And by what criterion are we to tell if a science is highly developed, other than its degree of parsimony? If the principle of parsimony is accepted, then it is for each side to show that it is more parsimonious than the other. Burt concluded that introspection should be among the methods of psychology, though it should certainly not be the only one.

Introspection is necessary, not only because it brings new questions to the fore; but also because it alone can supply much of the observational data needed to answer them We need to know what intervenes between the stimulus and the subsequent response; and here, so I have argued, introspection yields the most important clues [p. 238].

Burt's (1962) argument, then, seems to be that introspection as a method is not unique, but that

the data it yields cannot be obtained in any other way. This implies a contradiction. Burt rests his case, first of all, on the notion of the probabilistic nature of science, arguing that no scientist in any field would insist on absolute certainty before accepting a datum. But, as he goes on to say, the crux lies in the distinction between what is "public" and what is "private." Burt (1962) seems here to wish to deny any such distinction: "Strictly speaking, *every* first-hand observation is necessarily 'private'. Whether certain observations are treated as 'public' turns not on their specific or intrinsic nature, but merely on the context [p. 231]."

I think Burt's argument is open to objection, but in practice, the objections may not matter much. First of all, it may well be that whether observations are *treated* as public depends on the context, but that does not answer the question whether they *are* public. Now, in what sense is every firsthand observation "private"? This seems true in the sense that each individual experience is unique. First, each individual is unique, by virtue of different makeup, different history, etc. But even if an exact facsimile of an individual were produced, there must logically be two experiences, since to qualify as individuals the beings must at least be distinct in time and place. The experiences might be identical in content, but there would be no way of proving this with absolute certainty. But it does not follow that because there are always two experiences, there are always two things of which the experience is. The question as to whether there is a reality independent of observers has of course a long philosophical history. It seems to me that science, if it is to operate at all, must assume that this is so. But we could, in fact, rest the argument at the point of saying that there is a distinction between events that we may suppose to exist independently and those of which we cannot suppose this. The first are "public"; the second "private." In the second class we put experiences; in the first, stimuli and responses. In practice, the distinction is often not very important. On the "private" side, the difficulties of communicating experience have been exaggerated, as Burt pointed out. On the "public" side, exact replications are rather infrequent.

R. S. Peters (1953) pointed out that both Titchener and Watson were part of the "observationalist" tradition of science. Titchener held that we directly observe experience; Watson, that all we can observe is behavior. Later behaviorists such as Hebb say that we infer our knowledge of

private events from the behavior we see. In the case of adult human beings, this behavior is usually verbal; but in the case of nonverbal beings, it may be, for example, discrimination learning. This, however, raises the question of what it is that we infer. To say that a child, an animal, or another adult has "an image" seems a curiously artificial statement, unless we have from our own experience some notion of what sort of a thing an image might be. It seems odd, in other words, to suppose that "image" has exactly the same sort of intervening variable status as, say, "filter."

I am aware, of course, that a forceful movement, represented by writers such as Lacan, denies the whole possibility of applying to human beings principles of objective observation that derive from the physical sciences. (See, for example, Caws, 1968.) But this argument would lead us too far afield. Within the observationalist tradition, Peters criticized the insistence on method which was characteristic of both Titchener and Watson. Science is not such that there is any one method that guarantees success. Nor, indeed, are there methods that must be utterly proscribed. Rather, there are criteria for assessing any method as more or less useful. To put it another way, scientific "method" is a much broader concept than the "methods" of introspection or behavioral analysis. These are better regarded as techniques, being two of those in the scientist's repertoire. As Peters (1953) put it: "All that is required for an inquiry to be a theoretical science is that conscious attempts should be made to overthrow hypotheses [p. 719]." There seems no reason, in practice, why introspections cannot be used for this purpose, even though they be held to be logically distinct from other sorts of observation. If introspection conflicts with itself or with other data, this is no different from any conflict of results.

It might be argued that it is simply a matter of what we are interested in. Presumably both Titchener and Watson were happy for the other to pursue his own path, but each insisted that "you must not call it psychology." But to define a science either by its subject matter or by its techniques seems unhelpful. There is no way of saying in advance what will turn out to be relevant or useful. Rather, science as a whole is the enterprise of establishing statements that correspond with reality, and any one science is simply a group of loosely related enquiries, put together for convenience or because of demonstrable connections. Psychologists, it seems to me, are people who are

interested in the behavior and experience of men and animals. Like every scientist, the psychologist says with Molière "*je prends mon bien où je le trouve*." Introspection gives us information about experience. It yields some data otherwise inaccessible. It may besides bring to light facts that might otherwise be overlooked, or stimulate us to ask new questions. Like any technique, it has peculiar difficulties, especially when used in odd circumstances. These, however, are the natural hazards of science. I would suggest that the battle that began over 60 years ago, and which some are apparently still fighting, might now be amicably concluded.

Looking Back and Ahead in Psychometrics

HAROLD GULLIKSEN

*Educational Testing Service and
Lindquist Center for Measurement,
University of Iowa¹*

In presenting the history of psychometrics, I shall do so in terms of the various investigators who worked in this area, even though I would, in general, agree with James Thurber in doubting the "great man theory" of the development of science. He pointed out that some people think it was a great day and a critical event when Benjamin Franklin sent up his kite and brought down lightning, demonstrating its fundamental similarity to electricity (Thurber, 1937). Others feel, however, that this event was not particularly critical, believing that if Franklin had not done this, somebody else would have made the same discovery; and we can see that this was exactly what happened with the harnessing of steam and the invention of the gas engine. Franklin did not make these discoveries, and sure enough somebody else did.

"Looking back in psychometrics" for me takes me to 1929 when I was a graduate student at Ohio State University, and Thurstone gave a seminar on the theory and applications of the law of comparative judgment and the method of paired comparisons. Numerous topics, such as art, aesthetics, ethics, subjective values, etc., had previously been dismissed with "What can you do about field or topic X? It is all a matter of opinion, and opinions disagree." I was tremendously impressed by the idea that now there was a clear-cut theory and experimental procedure for a rigorous treatment of those areas that are entirely a matter of opinion, and it was essential for the use of the method that the opinions should disagree (see Thurstone, 1959, for a collection of his articles on scaling).

Following the advice of Albert Paul Weiss, the senior professor in experimental psychology at Ohio

State, I attended the University of Chicago summer school in 1929 and took a six-week course with Thurstone in which he covered test theory, scaling, factor analysis, and, I believe, mathematical learning theory. A week or two was spent on each of the four topics, and that was that.

A decade earlier, E. L. Thorndike (1918) perceived the necessity and possibility for such developments in quantitative psychology: "Whatever exists at all exists in some amount. To know it thoroughly involves knowing its quantity as well as its quality [p. 194]."

Computers

Indicating the developments of the last 40 years requires mention of the electronic computer. I was a research assistant for a year working on Thurstone's first study of primary mental abilities. The computational work in resolving a battery of about 50 tests into seven primary mental abilities meant that I was supervising a group of about 20 computer clerical workers for about a year. I recall Thurstone lamenting that his PhD candidates would not be able to do factor analysis dissertations because it would not be practical to employ such a crew for each PhD thesis. A few years ago, a research worker in the U.S. Civil Service in Washington, D.C., wanted some help in analyzing a set of attitude scales which he had given to different types of persons working under Civil Service, in order to see how the jobs could be changed to make them more attractive. He came up one afternoon, with his data on punched cards, and we started about 4:00 p.m. to run the preliminary error-detecting program, and we corrected the cards whenever errors were found. In all, including the scaling, correlations, factor analyses, and rotations, although the job was somewhat larger than the primary mental abilities one, we were finished about 3:00 a.m. the next morning.

¹ This article is a revised version of a speech presented at the spring meeting of the Psychometric Society, Princeton, New Jersey, March 20, 1972.

Requests for reprints should be sent to Harold Gulliksen, Division of Psychological Studies, Educational Testing Service, Princeton, New Jersey 08540.

Testing

During the past 40 odd years, we have come a long way, as you all know, since the publication of Thurstone's (1931c) first test theory text. In reliability theory the widely used K-R 20 and K-R 21 were developed (Kuder & Richardson, 1937), and we have now progressed to Kristof's (1972) reliability for vector variables.

Latent structure models have been developed by Lazarsfeld (1950, 1954) and by Birnbaum (see Lord & Novick, 1968). Lazarsfeld (1950, 1954) also pointed out that data on joint occurrences (Do persons who have a watch, for example, also have a fountain pen?) could be analyzed to detect underlying "latent classes." Bert Green (1951) developed a rigorous matrix solution for the latent class problem and demonstrated that it correctly determined the latent classes using artificial data for which the solution was known. As far as I am aware, no one has found a set of real data that clearly demonstrates the existence of independent, homogeneous latent classes as defined by Lazarsfeld. It seems to me, however, that Green's solution is important because of the clever use he made of third-order joint occurrences to give an analytical solution for the rotation problem. Although no one has used such a procedure, it appears plausible that other theories could be developed in which Green's use of third-order joint occurrences would give a precise analytical solution for the rotational problem.

Rasch (1960, 1966) presented a theory to test for the presence of a one-factor ratio scale in test data. Melvin Novick, Charles Lewis, and others have worked on Bayesian procedures. These and other developments have been presented and summarized by Lord and Novick (1968) in *Statistical Theories of Mental Test Scores*. The theory and practical applications of tailored testing are being investigated by Lord (1971), Cronbach and Gleser (1965), and others.

The foregoing developments, however, are still largely in the theoretical field. I hope they will have greater impact on the standard aptitude and achievement tests. As far as I am aware, there has been little or no impact on teacher-constructed tests used in grading classes. Instead, there is today what seems to be a serious movement away from any type of measurement in education, rather than an attempt to use better measurement methods.

In aptitude test development, the rule is to take validity coefficients seriously without raising the question, "Should this validity be high or low?" During World War II, while working on aptitude and achievement test development for the Navy, Norman Frederiksen and I obtained considerable experience in this area. At the gunners' mates school, we found that the validity of the reading test was high, and the mechanical knowledge and mechanical comprehension tests had low validity. Checking on the tests originally used for grading revealed that the course as initially taught and graded emphasized verbal memorizing and repeating of material from the manuals and did not require that the students know how to disassemble and assemble the guns, or how to detect and correct malfunctioning. We worked for about six months and developed identification and performance tests that measured the objectives given to us by the gunners' mates school. These tests ensured that students were judged on the basis of their ability to disassemble and assemble the guns and to detect and correct malfunctioning, which were the objectives of the course as stated to us by the instructors. The initial validity pattern with high validity for the reading test and low validity for the mechanical knowledge and comprehension tests was not reasonable in view of the stated course objectives. The validity pattern which was found after introduction of the new testing program, based on the objectives stated by the instructors, indicated that the students were coming much closer to learning what the instructors wanted them to learn. On the basis of grades on the new achievement testing program, the validity of the reading test took a nose dive, and the mechanical comprehension and mechanical knowledge went up. The same thing happened in basic engineering, where the arithmetic test showed highest validity initially.

What had happened in the basic engineering course was that 1 of the 12 weeks was devoted to shop arithmetic, and the grades for that week ranged from very high to very low. The other 11 weeks were devoted to actual practice in the shop, using lathes, drill presses, saws, etc. The student's performance was rated by instructors who watched him work and checked various pieces he turned out—grading them on closeness of agreement with initial specifications. The grades for these 11 weeks were found to have very low variability, being mostly from 80 to 85 on a scale of 100. Apparently the instructors did not think that the students showed a high level of performance, but

they were usually reluctant to give a very low mark. It is a well-known fact of test theory that if one grade with high variability is averaged with a number of other grades of low variability, the final average will correlate highest with the one component with large variability. The problem here was to develop grading procedures for the 11 weeks of shop work that were more objective than the instructor's judgment and that would be sensitive to the students' variability if they did vary in performance. Nicholas Fattu worked for a year developing gauges to measure the products quickly and accurately, and, on the basis of the achievement measures, the validity of the arithmetic test dropped and that of the mechanical aptitude tests went up. Similar results were obtained in the torpedoman's and other schools. Again, we achieved the same result as in the gunners' mates school. The validity pattern found after the introduction of the new performance testing program, based again on the school objectives as stated by the instructors, was a reasonable one, indicating that the students were approximating the objectives desired by the instructors. Some of this work has been written up in Stuit (1947), especially Chapters 12, 13, and 15. The interesting point demonstrated here is that a pattern of validity coefficients over a set of aptitude tests can indicate, by its reasonableness, or unreasonableness in agreeing with course objectives, whether or not the teaching, testing, and grading procedures are in agreement or in disagreement with the objectives of the instructor.

I think school and college grades are in need of similar scrutiny. For example, the spatial relations test of the College Board showed good validity for grades in some engineering drawing classes and poor validity for other engineering drawing grades. Such results would be expected if these courses, which were all given the same name, engineering drawing, were in fact quite different and were graded on different bases. One possibility is that the engineering drawing courses for which the spatial relations test showed good validity were courses that required the student to use spatial visualization in his course work. The other courses with the same name, engineering drawing, but with low validity for the spatial relations test were courses taught, tested, and graded so that the student did not need to use spatial visualization to be successful in the course. A general discussion of such problems under the title "Intrinsic Validity" can be found in Gulliksen (1950).

An article by Plotkin in the March 1972 issue of the *American Psychologist* discussed problems in the area of the validity of tests brought to the fore by the Equal Employment Opportunities Act of 1964.

I feel sure that Benjamin Shimberg and his associates, who are working at the Educational Testing Service on such things as tests for auto mechanics, will not accept the conclusion that the major important quality for an automobile repairman is high verbal ability, on the basis of validity studies, but will see to it that the criteria are changed so that the important abilities are mechanical skill, trouble shooting ability, etc.

Some years ago, in looking over validity coefficients for the Differential Aptitude Test, I noticed that for one school the best predictor of grades in Latin was the clerical test (.47). For the other tests of the Differential Aptitude Test, the correlations with Latin grades ranged from a low of $-.37$ for mechanical reasoning through $-.02$ for verbal reasoning, to a high of $.19$ for sentences. It was pleasing to note that this was not generally true for all of the schools studied. But it would be even more pleasing if some steps had been taken to alter the teaching and grading procedures in that school. Other studies by the Psychological Corporation showed that higher educational level goes with higher clerical ability (see Bennett, Seashore, & Wesman, 1959, pp. 48, 79; 1966, pp. 5-42). This may indicate an undue emphasis on clerical ability for college selection.

In 1939, Truman Kelley noted that only the verbal and quantitative abilities seem to be important as far as academic work in schools and universities is concerned. He spoke of the numerous abilities that even then were being isolated by factor analysis and indicated his fear that "many of the factors thus far 'found' approach pretty close to the limit of no importance [p. 142]." This may well be true of many of the 150 or so factors in the French (1951) monograph, but before reaching any such conclusions, the school's teaching, testing, and grading procedures should be studied carefully and revised where necessary. My own judgment would be that when this is done properly we will find that verbal and quantitative do not exhaust the list of useful abilities.

In 1901, Clark Wissler, while getting his PhD with James McKeen Cattell at Columbia University, investigated the validity of a number of tests for predicting grades at Columbia. The validities for predicting grades at Columbia. The validities ranged from $-.02$ for reaction time to $.19$ for logi-

cal memory. During the seven decades since then, aptitude and standardized achievement tests have advanced tremendously. However, I think the evidence is that college grades are now about the same as they were at the turn of the century. Wissler (1901) reported that the correlations of grades ranged from a low of .30 for rhetoric and French to a high of .75 for Latin and Greek, which I believe would be very similar to the correlations obtained today.

During recent decades there have been a few attempts at improving the quality of college exams and grades. An example is the work of the examining office at the University of Chicago during the 1930s and 1940s under the direction of L. L. Thurstone and Ralph Tyler. The Chicago faculty later abandoned this program.

The great need we have now is not for the improvement of aptitude tests, but for improvement in the criteria against which they are evaluated, including not only grades for four years in college, but activities and achievements during the 40 years after college.

Scaling

In the early 1930s, Thurstone's interests changed from scaling to factor analysis. For the next decade, development in the scaling area was very slow. Marion Richardson and I asked Gale Young and Alston Householder about the problem of determining dimensionality and a coordinate system for a set of points from the interpoint distances. They solved the problem and published the Young and Householder (1938) paper on multidimensional scaling. The applications of this method by Marion Richardson and Klingberg appeared at about the same time. Otherwise, not much appeared until Torgerson (1951) developed the theory and verified a section of the Munsell color system in his thesis. Messick (1956) applied the method to attitude scales a little later. Since then, the development of scaling theory has been tremendous: the law of categorical judgment, the method of successive intervals, and statistical tests for fit of data to theory. These developments are presented in Torgerson's (1958) *Theory and Methods of Scaling*. Since then, there has been the extension to take care of individual differences, which makes the methods far more useful in attitude measurement and other applications in social psychology (see Carroll & Chang, 1970; Helm & Tucker, 1962; Tucker, 1972; Tucker & Messick, 1963). Luce

and Tukey (1964) developed the theory of conjoint measurement and showed the independent foundation on which psychological measurement rests. Bock and Jones (1968) gave rigorous estimation procedures. The theory has been developed by Suppes and Zinnes and Tversky and others (see Krantz, Luce, Suppes, & Tversky, 1971) so that measurements from psychological scaling are not dependent on other methods (see Luce, Bush, & Galanter, 1963a, 1963b, 1965a, 1965b). Indow and his group in Japan, Ekman and his group in Sweden, and Stevens in the United States have been active in the development of theory and applications of scaling.

Applications of scaling techniques to linguistics and free recall are illustrated by the work of John B. Carroll (1971) and Friendly (1972). My own work (Gulliksen & Gulliksen, 1972) has also illustrated the application of scaling and factor techniques to attitudes toward work and leisure in cross-cultural comparisons. Coombs (1964) and his co-workers developed a nonmetric multidimensional unfolding procedure, using this method to study confusions of Morse code signals, and showed two dimensions in the subset of 10 signals studied.

As indicated above, there have been numerous applications of scaling techniques by research workers in various academic university settings. However, when we consider the various applied fields in which linear and multidimensional scaling could be used, the picture is different from the development of theory and applications in the academic setting. The various polling organizations report nothing but total percentages, sometimes broken down by various pre-formed categories, such as education, sex, rural-urban, etc. I have never seen a single instance in which a factor analysis of a set of observations is given, so that various points of view, or clusters of opinions, can be found. Robert Tryon (1955) reported a factor analysis of voting areas around San Francisco and found that the various indices available formed a three-factor system. He suggested that voting might well be associated with these factors, so that one would get better prediction by repeating such a study in connection with a new election poll and using these factors as independent variables in adjusting the polling results. As far as I am aware, no polling group has paid any attention to such possibilities.

Green and Carmone (1970) and Green and Rao (1972) showed how multidimensional procedures could give valuable information in consumer sur-

veys. Applications in behavioral sciences were given in Shepard, Romney, and Nerlove (1972). Applications in marketing research were presented by Bass, King, and Pessemier (1968). The use of scaling methods in studies in perception by Carroll and others are reported in Carterette and Friedman (1974). Bell laboratories has compiled a bibliography of recent studies and applications of multidimensional scaling (Harris, 1972). It is pleasing to note that the scaling techniques have recently been utilized in a number of research areas and applied fields.

Factor Analysis

With respect to factor analysis, the initial papers presenting the principal components and other methods were published by Thurstone (1931a, 1931b, 1933) and Hotelling (1933), following earlier work by Spearman and Holzinger. Thurstone presented his problem to Bliss in mathematics and Bartky in statistics one noon at the Chicago Quadrangle Club. He explained that he had a square symmetric array of numbers and wanted to express it in terms of summed products of a smaller array. Their reaction was, "Oh, you mean the square root of a symmetric matrix." In this way Thurstone learned that matrix theory existed and was relevant to the factor problem, so he embarked on a year or two of tutoring and published *The Vectors of Mind* (1935), followed later by *Multiple Factor Analysis* (1947), giving a concise summary of the crucial aspects of matrix theory and their use in factor analysis. Prior to the advent of electronic computers, approximations such as the centroid method, with largest correlations used as initial estimates of communalities, were widely used because of their practicality.

I remember Samuel Wilks remonstrating about this. He said, "We know a good method, the principal components, based on least squares, that gives a best fitting reduced rank matrix. Why can't you use that instead of these ad hoc approximations whose properties are unknown?"

Since then, Lawley and also Jöreskog (1970) with Gruvaeus and van Thillo have presented the theory and associated practical computer methods. Kaiser's (1970) little jiffy is very widely used. Tucker has given us the procedures for double-centered matrices (Tucker, 1956), the interbattery matrix (Tucker, 1958), and three-mode and multi-mode analysis (Tucker, 1966a). Harris (1962, 1963) presented relations among factor theories

and cautions that should be observed when attempting to measure change. Guttman (1971) presented some extensions and applications of his facet theory. Horst (1961) gave possible applications of generalized canonical correlations. McDonald (1967) gave us his nonlinear factor analysis. Arbuckle (1970) developed a procedure using the Toeplitz matrix as the error matrix instead of a diagonal matrix, so that the factor procedures may be applied to matrices where it is reasonable to assume "stationary error," as in analyzing nerve potentials.

Factor analysis theory and associated electronic computer programs are in a reasonably well developed state. As to applications of the methods, it has been mentioned previously that numerous aptitude test batteries have been analyzed, so that psychologists have some reasonable notions regarding the basic abilities represented in aptitude tests.

The factor methods have, however, been only sketchily used in other fields where they would be extremely valuable. Harman (1967) devoted about a page of his text to indicating applications in economics, sociology, physiology, etc., but the impact of these factor studies on the fields indicated has been minimal.

Schiffman and Falkenberg (1968) presented an interesting study of matrices with stimuli designating rows, by retinal cells designating columns, or stimuli by taste neurones, that give interesting pictures of the structure of these sensory systems. In the study of retinal cells, the stimuli spread out in a curve—violet, blue, green, yellow, orange, and red—while in the same space the retinal cells clustered three in the blue area, four in the green area, and four in the red area. The factor analyses demonstrated that some cells were highly sensitive to blue and not to other colors; some were highly sensitive to green, and others sensitive to red. This result is in agreement with a three-color (blue, green, and red) theory of color vision. If a four- or a two-color theory represented the mode of functioning of the retina, one would expect to find four or two clusterings of cells. For taste, a definite three-dimensional structure was obtained, but the details are not so clearly interpretable.

Memory is another field in which factor analysis would be extremely valuable. For example, Paul Kelley's (1964) study demonstrated that memory span is a factor which includes visual and auditory material, as well as nonsense and meaningful material. However, when one deals with longer lists, so that it takes a number of repetitions to memorize

them, then rote memory differentiates from memory for meaningful material. That is to say, when Ebbinghaus introduced the nonsense syllable, as he thought to simply control for the irrelevant factor of possible differences in previous associations, he was unwittingly shifting to measurement of a different ability. Recently, there has been great emphasis on what is termed *free recall*, which means that the material, though meaningfully organized, is presented randomly, to see the extent to which the subjects will make use of the organization in recall. Again, as with Ebbinghaus, it is assumed that this is simply another interesting procedure for tapping the memory function. However, as far as I am aware, no factor studies have been made including the free recall, the rote, and the meaningful memory where the order of presentation must be the order of recall. We do not know whether the free recall ability is the same as the previously established rote or meaningful memory, or whether a new ability has been introduced with this new procedure. Stake (1961) presented evidence indicating the possibility that the change from free study such as Ebbinghaus (1885) used, to the memory drum, introduced by Müller and Schumann (1894) merely as an added experimental control, may have altered the ability being measured.

Eight indices of "excitatory potential" (a useful hypothetical construct) were used by Lloyd Humphreys (1943) in a conditioned eyelid experiment. He found two factors. Acquisition *amplitude* and extinction *amplitude* loaded on one factor, while acquisition and extinction *latencies* loaded on a different factor, along with extinction frequency. Acquisition frequency loaded equally on both factors. That is to say, the experimenter's selection of one or another from a set of possible indices may really be changing the hypothetical construct being measured.

For decades it has been asserted that "intelligence is the ability to learn" (e.g., Binet, 1909, especially p. 146; Buckingham, 1921, especially p. 273; Dearborn, 1921; Peterson, 1926, especially pp. 268 & 276; Pyle, 1921). This view that intelligence is the ability to learn has been critically examined (e.g., see Peterson, 1926; Simrall, 1947; Woodrow, 1946). Psychologists have devised numerous clever tasks in rote learning, meaningful learning, concept learning, motor learning, etc., such as mirror drawing, pursuit rotor, reversal learning, etc., which require an ability to learn, that can be measured by time, errors, or trials taken to reach some criterion, or by parameters of

some learning curve fitted to the data. In only a few cases have such studies also included a few of the standard test scores that may be related to intelligence.

Studies in this area by Duncanson, Stake, Allison, Manley, Games, and Bunderson, reviewed in Robert Gagné's (1967) *Learning and Individual Differences*, have indicated that there are a number of different abilities represented by the different learning tasks, as well as a number of different abilities represented by the intelligence or ability tests. So far, *some* of these abilities seem to be unique to measures of learning, or to test scores, but there are some factors that have loadings on both the learning scores and the test scores. A clear answer as to the relation between aptitudes as measured by tests and learning abilities as measured by various learning tasks devised by psychologists is not available at present. The topic is in need of much further research.

For the last 40 years there has been a profusion of factor analyses of batteries of aptitude tests, but there are numerous other areas in learning, memory, physiology, nerve potentials, economics, political science, sociology, etc., in which factor analysis would be extremely valuable and in which only a few studies have been made.

Learning

With respect to mathematical learning theory, Thurstone (1930a) presented a mathematical derivation of an equation of the learning curve based on an urn analogy, which turned out to also be derivable from Thorndike's Law of Effect (Gulliksen, 1934). Thurstone (1930b) also showed how this theory could be applied to determining a functional relationship between learning time and length of task, and to separating learning ability of the individual from the difficulty of the task, using factor methods. I presented an analytical procedure that separated learning ability from initial performance (Gulliksen, 1942).

During the 1950s, a variety of learning models were presented based on stimulus sampling ideas (Estes, 1956), stochastic processes (Bush & Mosteller, 1955), stepwise increases or decreases in strength of correct and incorrect responses (Audley & Jonckheere, 1956), and various models suggested by Bower, Trabasso, Atkinson, Suppes, and others.

In general, these more recent models tended to have two characteristics:

1. Response strengths, or response probabilities, changed by finite amounts with each trial. The substitution of differentials for deltas was believed to be an extremely inappropriate step that must be avoided.

2. In order to obtain good parameter estimates, it was usually assumed that all subjects in a group could be regarded as giving estimates of the same parameter values so that the record of the group of learners was analyzed to determine one set of parameters.

There are several questions introduced here that it seems to me should be subjected to careful experimental investigation, rather than being settled by assumption:

1. We now have a variety of stochastic, or finite, step models, and also older continuous models. Both of these types of models should be tried out on various types of learning data. It is perfectly possible that different theories will be best for different types of tasks. The same type of theory may well not fit conditioned escape response, maze learning, visual shape discrimination—with attention to transposition, paw retraction to avoid a shock, conditioned emotional reactions such as rapid breathing, etc. For example, there is evidence that conditioned paw retraction does not transfer from the right to the left brain in split-brain animals, while increased breathing rate transfers very rapidly. We need now a large number of studies in which various stochastic and continuous models are tried out on various types of learning data.

2. I feel that the primary stress should be on using learning parameters that are psychologically meaningful. By this I mean parameters determined for each individual such as difficulty of task, learning ability, initial preference, and final performance on the task. Such parameters are, in general, different for each individual and characterize important individual differences. These parameters seem to me to be meaningful in understanding differences between learning tasks and differences between individuals in learning these tasks. Parameters such as number and length of runs of errors, average and variance of learning parameters, and number of alternations have been frequently or usually used with stochastic models. Such parameters characterize the group as an entity and do not differentiate the differing characteristics of different individuals. They seem to me to be parameters selected because they fit with the stochastic

models, rather than because they have any interesting psychological significance in understanding the learning process or the differences between learning tasks and between learners.

Bush and Mosteller (Chap. 15 in Bush & Estes, 1959) gave a comparison of eight different learning models, with respect to their agreement with Solomon and Wynne's data on shock avoidance by 30 dogs given 25 trials each. The comparisons are entirely in terms of means and standard deviations of distributions of a number of variables, such as number of trials before first and second avoidance, total number of shocks, number of alternations, number of trials before the first run of four avoidances, etc. Such parameters characterize the group as a whole and need to be supplemented by parameters that indicate the differing abilities of different individuals. Instead, it is assumed either that the basic parameters are the same for all animals, or else that the parameter varies according to some specified distribution. This seems to me to be an approach dictated basically by the characteristics of the stochastic approach, rather than by the psychologically interesting properties of learners and learning tasks. Determination of parameters for each learner offers a much better way of understanding the learning process, in terms of parameters of individuals, and parameters of the tasks, such as initial ability and learning ability, and difficulty of the task.

3. Merrell (1931), Sidman (1952), and Estes (1956) pointed out the difficulties involved in using group or average learning curves, yet obtaining a single set of parameters for the average learning curve is still a usual procedure. Is it legitimate to regard learning parameters as the same for all subjects in a group, or do some subjects have definitely better learning ability or initial performance than others do? Again, the answer may be different with different types of learning problems and with variations in difficulty of the problem. There are at least two possible approaches that should be tried on this problem of individual differences in learning parameters. One approach proposed, and tried out on some sets of data by Tucker (1966b) and by Weitzman (1963), is a principal components analysis of a matrix of learning curves. The method gives a set of k learning parameters for each individual, and k generalized, or master learning, curves. In the special case in which k is equal to one, then it is legitimate to use the group or average learning curve.

4. Parameter estimation for individual learning curves for the finite step models is a difficult problem. Procedures have been devised by Ramsay (1970), Wainer (1968), and Best (1966) for parameter estimation for individual learning curves. Using Monte Carlo data with known parameters, Ramsay (1970) found that the input parameters were not recovered except for the limited case of only two parameters, initial probability of a correct response, and the effect of reward of a correct response on the strength of the correct response. Ramsay also felt that negative parameters, which allowed a decrease in response strength, should not be permitted because this might lead to negative response probabilities. Best's (1966) procedure allowed for the possibility that the strength of the incorrect response would be decreased by punishment for an error. If the fitting problem is satisfactorily solved, then various stochastic and continuous models could be compared with respect to parameter determination for individual rather than group learning curves.

5. One of the great handicaps in the study of learning has been the impossibility of obtaining evidence on reliability by replication. When a learning curve has been obtained, a second one on the same problem for the same individual is impossible, because he already knows the solution and cannot learn it again. If one tries a different problem, there is the question of how similar the two problems are, and also the question of positive or negative transfer. If one tries the same problem with another individual, then there are the possibilities of different learning abilities for the different individuals. Sperry (1961, especially p. 1753; 1964, especially p. 48) felt that his work with split-brain preparations offered an opportunity for replication from left to right brain with what was essentially a duplicate subject. So far the evidence here is conflicting. Meikle, Sechzer, and Stellar (1962), working with cats suspended in a harness and learning to lift the front paw to avoid a shock signaled by stroking the shoulder, found (for three animals) a very good linear relation between number of trials to criterion for right-brain and left-brain learning. Phillip Best (1966) analyzed visual discrimination data from an experiment by Meikle and Sechzer (1960) and found a strong linear relation between first- and second-side learning in split-brain cats. By contrast, Ian Steele Russell (Russell & Kleinman, 1970), working with functionally split-brain rats on a conditioned escape response, found that for a given difficulty of the

problem there was a zero correlation between trials to criterion for left versus right brain. He pointed out that this is consistent with the view of learning as a finite step process. Recent work by Guliksen and Voneida also found marked dissimilarity between right-brain and left-brain learning in split-brain cats.

Another problem is raised by the probability learning situation. When, for example, one stimulus is rewarded 70% of the time and the other rewarded 30% of the time, some investigators report that the subjects choose the stimuli about 70% and 30%, respectively. This behavior is known as *matching* and would result in $.7 \times .7 + .3 \times .3 = .58$ success. Choosing the "70%" stimulus all of the time would result in 70% success. This is known as *maximizing behavior*. Stimulus sampling theory predicts matching. Maximizing is frequently found, however. Wainer (1968) found that maximizing behavior was the rule and succeeded in modifying the stimulus sampling theory so that with different parameter values it would predict either maximizing or matching. His data gave good agreement with the generalized theory and showed maximizing rather than matching. He devised methods of fitting parameters to individual curves.

Richard Rose (Rose, Beach, & Peterson, 1971) at the University of Washington recently reviewed the major studies in this field and concluded that "probability matching though widely accepted by psychologists is not found when individual records are examined, instead of group averages. The individual response probabilities are much further away from matching or other theoretical values than would be permitted by the most generous interpretation of extant theories [p. 11]." In my view this points to the desirability of estimating parameters for individual rather than group curves.

In this review, I wish to make clear the difference between assuming distributions of parameters for the group and *also obtaining parameters characteristic of each individual*, which is the procedure usually used in factor analysis and testing (and which can be used in scaling), as contrasted with the customary procedure in stochastic learning theory (illustrated by the analysis of the Solomon-Wynne data) which assumes distribution functions and parameters for the group and stops there without any attempt to detect the best versus average versus poorest learners. I think such an approach that makes no attempt to characterize differentially the different individuals in the group is inappro-

appropriate especially for studying learning in which one of the central interests would be individual differences, if they exist. Also, if learning tasks were found in which all individuals of a species performed alike except for random differences, this would be very interesting and important, but can be ascertained only if individual parameters are obtained and found to differ only randomly from individual to individual.

In the field of mathematical learning theory, it seems to me that a great deal of work still needs to be done on parameter estimation for individual learning curves and in comparing various stochastic and continuous models. By contrast, in the fields of test theory, scaling, and factor theory, the theory including parameter estimation, significance testing, and variance components analysis procedures are reasonably well developed. Test theory, though adequately utilized in standardized testing programs, has not yet had much impact on the teacher-constructed tests and on grading procedures. As indicated above, it is necessary to keep in mind the objectives of the instruction. The various testing and grading procedures should be examined to see if they reflect adequately the objectives; and, as pointed up in the account of work for the Navy, interesting clues regarding the adequacy or inadequacy of testing and grading procedures can be obtained from studying the pattern of high- and low-validity coefficients for different aptitude tests. Recently, scaling, especially multidimensional scaling, has received considerable attention from workers in certain applied fields and in some research areas, but its use could be more widely extended, as for example in election polls. Scaling methods together with factor analysis of the data could give information on possible differing opinion patterns of different individuals that might well be more informative than limiting the analysis to group averages and percentages. Numerous batteries of aptitude tests have been factor analyzed—but application of factor analysis to economics, sociology, physiology, etc., is just beginning to get under way.

Quantitative psychology, which could be reasonably adequately covered by a six-week course in 1929, has moved a long way in the directions indicated by Thurstone (1937) in his Dartmouth address as retiring first president of the Psychometric Society, "Psychology as a Quantitative Rational Science."

Distribution by Sex of Authors and Editors of Psychological Journals, 1970-1972

Are There Enough Women Editors?

MARTHA TEGHTSOONIAN *Smith College*¹

The present-day counterpart of the female suffrage movement faces a situation at once more complex and more ambiguous than that which existed 50 years ago. Since the passage of the Nineteenth Amendment in 1920, there no longer are major legal barriers to equality for women in this country. Yet, accumulating evidence indicates a widespread failure of women to achieve equality with men in professional status, job quality, and salary (see, e.g., Chase, 1971; Levitin, Quinn, & Staines, 1971; Rossi, 1970). An extensive survey of departments of psychology, reported by the Task Force on the Status of Women in Psychology (Survey, 1971), showed a steady decrease in the percentage of women from undergraduate majors (45% female), through graduate students and PhDs, to assistant, associate, and full professors (7% female). The fact is that proportionally more men than women psychologists continue up the ladder of professional advancement.

The finding that women occupy lower responsibility and lower salary positions proportionally more often does not in itself demonstrate sexual bias in hiring and promotion. There are two classes of explanations for such an outcome. One class attributes the differences to characteristics of women themselves: lower aspirations, lower productivity, and lesser degree of professional com-

mitment, for example. These explanations assume that the reinforcement contingencies for professional behaviors are defined and administered without regard to the sex of the performer, and that different outcomes therefore depend only on differences in job performance. The other class of explanations attributes the difference to the policies of institutions and professional organizations: different pay scales for women, differential hiring and promotion practices, and nepotism rules, for example. These explanations assume that there are two sets of reinforcement contingencies for professional behaviors, one for men and one for women, and that the one for men is designed to reinforce job performance at a higher rate than the one for women. Data bearing on these hypotheses are not extensive; however, Astin (1972), showing that academic women in psychology hold low-status positions and are paid low salaries relative to their male colleagues, concluded: "Although it could be argued that the woman psychologist's lower rank, lower salary, and lack of tenure are a consequence of merit consideration . . . , these analyses suggest strongly that such is not the case [p. 380]." In particular, she showed that inequalities in reward remained when men and women were equated for publication rate.

The present study investigated one type of professional behavior—publication of research in psychological journals—and one type of reinforcer—appointment to journal editorship. That publishing research is considered an important component of the psychologist's job goes without saying: Salary, promotion, and professional standing may depend on it. It seems reasonable to assume that the post of journal editor constitutes a mark of recognition from one's colleagues of the excellence of one's work, and an indicator to others in and out of the profession of high professional standing.

¹ Some of the data on which this article is based were reported at the meeting of the Eastern Psychological Association, Boston, Massachusetts, April 1972, under the title "Sexual Bias in the Selection of Editors of Psychological Journals?" The author is grateful to Ann Peterson, who tabulated the 1971 data, and to Smith College, which made it possible for her to do so through a Sloan Foundation Summer Research Grant. The author also thanks Robert Teghtsoonian for his criticisms of the manuscript and for suggesting the analysis of citation rate.

Requests for reprints should be sent to Martha Teghtsoonian, Clark Science Center, Smith College, Northampton, Massachusetts 01060.

Can women psychologists who maintain the same rate of publication as their male colleagues have the same expectation of editorial appointment?

In an earlier period, 1929–1949, it was unusual for women psychologists to become journal editors. According to Mitchell (1951), 20% of the Fellows of APA during that interval were women, but of the 187 editor years of APA journals, a woman accounted for only 1! A sample of psychological journals in 1970–1972 was examined to discover whether the situation had changed in the intervening 20 years.

Eleven psychological journals publishing experimental reports and considered by the author to be of moderate to high prestige were selected to represent a variety of fields. They are referred to as Sample A (see Table 1). If a journal published three to six issues in a year, all were included; if there were more than six, only six issues during the year were included. An editor was defined as one whose name appeared on the cover of an issue as (a) editor (hereafter designated as principal editor); (b) associate editor; or (c) consulting editor, advisory editor, member of an editorial board, etc. Separate tabulations were made for the first two categories and for all three categories combined. Editor's first (or middle, if first was represented by an initial) name was classified as "usually given to a female" or "usually given to a male." Consultation of membership directories and letters of inquiry permitted the eventual classification of all editors. (For reasons discussed below, editors with foreign affiliations, about 3% of the sample, were excluded.)

The results are shown in Table 1. In the sample of 120 editor years for principal and associate editors, only 1 was accounted for by a woman. In this respect, there has been no essential change since Mitchell reported in 1951. In the sample of all editors, totaling 322, 316, and 319, for 1970, 1971, and 1972, respectively, the number of women was 14, 14, and 19, that is, 4.3%, 4.4%, and 6.0%. Journals varied rather widely, with 0%–12% of the editors being women. (The modal number of women editors per journal was 1. Is this evidence of tokenism?)

As women comprise 24% of psychologists (Untitled, 1971) but only 5% of editors, it is clear that women psychologists are a great deal less likely than their male colleagues to become editors. When Mitchell presented similar findings in 1951, she asserted that they showed discrimination against women. Boring (1951) replied that the

fault lay, not with APA, but with women themselves, who preferred applied fields in psychology, who failed to be "professional fanatics," and who failed to seek prestige through the publication of books. The question, then, is whether there is a bias toward men in the selection process for editors, or whether unbiased selection operates on a pool of potential editors in which there are proportionally fewer women than there are in the profession as a whole. Several factors that would operate to reduce the number of potential female editors can be hypothesized: (a) *publication*—women may publish less than men; (b) *contribution to published research*—women may less frequently be major contributors; (c) *quality of research*—women may publish research of poorer quality; (d) *age*—women publishing research may be younger than their male colleagues; (e) *rate of publication*—women may publish fewer papers per author than do men. Subsidiary data analyses were carried out to check these hypotheses. In addition, the generalizability of the findings for percentage of women editors, and for Hypotheses a and b were checked by performing the same tabulations for a second sample consisting of all 1972 APA journals publishing primarily research reports.

Some Possible Explanations of the Small Number of Women Editors

PUBLICATIONS

If women do not publish as much as men, this would readily account for a lower probability of women being selected as editors. The percentage of authors who are women was tabulated for each of the journals. Authors of all articles except book reviews and monographs became part of the sample. Authors' names were classified in the same way as editors' names. (Since most editors have American affiliations, all authors and those few editors with foreign affiliations were eliminated from the sample. Overall, about 3% of the editors and 15% of the authors listed foreign affiliations.)

Initially, about 7% of the authors' names were unclassifiable. For the 1970 sample only, a letter explaining the purpose of the study was sent to each unclassifiable author, with a prepaid, addressed postcard and a request to return it after checking the appropriate sex. Unclassified names eventually represented .28% of the 1970 sample; the return rate on postcards was 90%. Originally

TABLE 1

Number of Editors, Authors, and First Authors and Percentage Who Were Women for Eleven Psychology Journals in 1970 and 1971 and for Sixteen Journals in 1972

unclassifiable names were slightly more likely to be male (88.2%) than eventually classifiable names (85.7%). The difference is small enough, and the labor required to obtain complete classification so great, that for the years 1971 and 1972, unclassifiable names were simply eliminated from the sample.

Table 1 shows that, in 31 of 33 comparisons, the percentage of authors in a given journal year who are female is larger than the percentage of editors for that same journal year who are female, sometimes substantially so. Over the whole sample, 14.2%, 13.9%, and 15.8% of the 4,532 authors were women, for 1970, 1971, and 1972, respectively.

This value of about 15% can be compared, first, to the 24% of APA members who are female. Why should the percentage of women authors be lower than that of women psychologists? A possible explanation is suggested by the division memberships listed in Table 1, where each journal is accompanied by the APA division whose interests it most closely reflects; except for Division 7, the percentage of women members is less than 24. The expected number of women authors can be calculated by multiplying the number of authors for each journal by the percentage of female membership in the related division; the result is 706, or 16% of the total, very close to the obtained value. By inference, then, the average woman in the divisions represented in Table 1 publishes research about as frequently as the average man.

The value of 15% women authors can also be compared to the 5% of editors who are women: Women are not selected as editors as often as one would expect from their numbers as authors.²

CONTRIBUTION TO PUBLISHED RESEARCH

It may be argued that women are less frequently initiators of research, more frequently assistants and technicians. This argument received some support from the finding that, in this sample, 55.4% of the males were first authors, but only 46.4% of the females were first authors.

However, as Table 1 shows, for 29 of the 33 comparisons, the percentage of first authors who are women for a given journal year is greater than the percentage of editors who are women in that journal

year. The percentage of all first authors in the sample who are female is 12.5%, compared to the 4.9% of all editors who are female.

QUALITY OF RESEARCH

A hypothesis to account for the discrepancy between the proportions of women editors and authors is that the work published by women is on the average of lower quality. A readily obtainable and reliable index of quality of research is frequency of citation; Myers (1970), investigating the relation between journal citations and scientific eminence, concluded, "The evidence . . . shows that psychologists who are judged to be scientifically eminent on the basis of a variety of other independent criteria are also those most frequently cited in the current journal literature [p. 1047]." This finding suggested that the quality of contributions from women psychologists could be assessed by comparing the citation rates for men and women authors: If women match men in the quality of research, their work should be cited as frequently.

This hypothesis was studied for one journal, the *Journal of Experimental Psychology*. As an APA journal, a journal of high prestige, and one that publishes research from a variety of fields, it also seemed to be a journal of interest to many psychologists. For the years 1961 (Volume 61) and 1971 (Volumes 87 and 88), citations were counted, following the rules listed by Myers (1970): (a) No self-references were counted; (b) only one citation per author was counted from the list of references for a given article; (c) one citation was counted for each author of multiple-author references. Additionally, no references to unpublished work were included in counting citations. The name of the author for each citation was classified by sex. A name originally unclassifiable (because only initials were given and the sex of the author was unknown to the classifier) was checked by looking at the cited reference if it was available.

For 1961, there were 826 citations, of which all but 9% were classified eventually. Of the 826, 42% were from references 1-5 years old; 31%, 6-10 years old; 10%, 11-15 years old; the remainder, 17%, were older than 15 years. Of the 753 classifiable citations, 9.8% were female. Figure 1 shows percentage of female citations for five-year intervals preceding 1961. In the volume from which these citations came, there were no women editors, while 15% of the authors and 9% of the first authors were women.

² A similar disproportion between percentages of editors and authors who are female was reported by Schuck (1970) for the *American Political Science Review* from 1960 to 1969.

Figure 1. Percentage of female authors of articles cited in the *Journal of Experimental Psychology* in 1961, Volume 61, and 1971, Volumes 87 and 88, classified by the age of the article at the time it was cited.

For 1971, there were 1,847 citations, of which 12% remained unclassified. Of these 1,847 citations, 51% were from references 1-5 years old; 29%, 6-10 years old; 10%, 11-15 years old; the remainder, 10%, were older than 15 years. Of the 1,618 classifiable citations, 11% were female. Figure 1 shows percentage of female citations for five-year intervals preceding 1971. In the volumes from which these citations came, there were 7% women editors, while 11% of the authors and 10% of the first authors were women.

Both in 1961 and 1971, the percentage of cited authors who were women was about 10. The percentage of women authors dropped from 15 to 11, but the percentage of women first authors remained the same, at about 10. Thus, women are cited in the *Journal of Experimental Psychology* about as frequently as one would expect from the proportion of women authors, although proportion of women first authors is less variable and perhaps more closely related to citation rate. There is no support here for the contention that women publish inferior work, and thus none for the hypothesis that a paucity of women editors reflects the poorer quality of women's research.

How far the results for this one journal can be generalized to other journals is unknown. At the least, one can say that the failure of the "lack of quality" hypothesis to account for disproportion-

ately few women editors for one journal makes it a less attractive hypothesis to account for the more general finding.

AGE

It has been suggested that the women who comprise 15% of the authors in these journals are, on the average, younger than the men who account for the other 85%. If a man has been professionally active longer than a woman, he is more likely to be chosen for an editorial position, other things being equal. There is no direct evidence on the age hypothesis. However, for the *Journal of Experimental Psychology*, percentages of women editors and authors were tabulated for 1966 (Volume 71). Thus, for 1961, 1966, 1970, 1971, and 1972, respectively, we have percentage of women authors: 14.9%, 13.4%, 10.5%, 11.0%, and 15.3%; percentage of women first authors: 9.2%, 7.2%, 12.5%, 10.2%, and 15.5%; percentage of women editors: .0%, .0%, 5.8%, 6.8%, and 8.1%. That is, there is no indication that the proportion of women authors has been increasing, as might be anticipated given the hypothesis that current women authors are younger than their male colleagues. It is also noteworthy that the citation rates for women remain relatively constant over time, as Figure 1 illustrates. There is thus no support for the notion that, while the proportion of women authors has remained constant, the quality of their research has improved. These data indicate that about 10%-15% of the work in the *Journal of Experimental Psychology* is contributed by women, that about 10% of the work cited is contributed by women, and that this has been true for at least the past 12 years. Over the same time period, the proportion of women editors has risen slowly, but has not yet reached the level to be expected on the basis of women's contributions.

RATE OF PUBLICATION

Perhaps women publish papers at a lower rate than do men. Two journals with a high percentage of women authors, the *Journal of Experimental Child Psychology* and the *Journal of Verbal Learning and Verbal Behavior*, were selected. For each journal, each name in the author indexes from 1965 to 1969 was classified as male or female; unclassifiable names were classified by directory search and inquiry only for multipaper authors; authors with foreign affiliations were not eliminated.

Each name was then classified according to the number of papers published in that journal in five years. Table 2 shows the percent frequency distributions for male and female authors for the two journals. Although the distributions for men and women were quite similar, a larger proportion of women than of men published only one paper, and there were proportionally more men who published four or more papers.

For each journal separately, the conditional probability that a male author would be an editor, given that he had published n papers, was calculated; for both journals, as n increased, the probability of being an editor approached 1. For each n , the conditional probability was multiplied by the number of women authors who had published n papers; summing over n ; one obtains an estimate of the number of women editors expected on the basis of their publication rates in the absence of sexual bias in selection. For the *Journal of Experimental Child Psychology*, 8.1 is the expected number of women editors, compared to the actual numbers of 4, 3, and 3.5, for 1970, 1971, and 1972, respectively. For the *Journal of Verbal Learning and Verbal Behavior*, the expected number is 3.7; the actual numbers are 0, 0, and 1, for 1970, 1971, and 1972, respectively.

COMPOSITION OF THE SAMPLE OF JOURNALS

In selecting Sample A, I followed the lead of other authors who have made similar selections on grounds that the journals represented a variety of fields and were of interest to psychologists (e.g., Jakobovits & Osgood, 1967; Mace & Warner, 1973; Myers, 1970; Over & Smallman, 1973). It may be objected, however, that since the basis for selection is not precisely specified, the sample is of unknown composition, and thus the results are not generalizable. To answer this objection, a new sample of all APA journals in 1972 was specified (with the exceptions of the *Psychological Bulletin*, the *Psychological Review*, and the *American Psychologist*, which have no editorial boards of fixed membership, and *Contemporary Psychology* and *Psychological Abstracts*). This is referred to as Sample B. The same classification of editors and authors by sex was carried out on this new sample. The results are shown in Table 1. The nine journals had 24 editors, principal or associate, of whom none were women. Of the total of 289 editors, 20.5 (one served for half a year), or 7.2%, were women. The total number of classifiable authors was 1,701,

TABLE 2
Percent Frequency Distributions by Author's Sex of Number of Articles in One Journal from 1965 to 1969

n	Journal of Experimental Child Psychology		Journal of Verbal Learning and Verbal Behavior	
	% male	% female	% male	% female
1	68	83	73	79
2	22	12	14	12
3	7	5	6	6
≥ 4	3	0	7	3

of whom 244, or 14.3%, were women; on the basis of APA division membership (excluding the *Journal of Applied Psychology*, for which there is no corresponding division), one would predict 18.6% female authors. The total number of classifiable first authors was 897, of whom 106, or 11.8%, were women; 54.5% of men were first authors, but 42.6% of women were first authors. For eight of the nine journals, the percentage of first authors who were women was greater than the percentage of editors who were women.

A comparison to Sample A shows that Sample B, the APA journals, has a higher proportion of women editors—7.2% to 4.9%—and a very similar proportion of women authors and first authors—14.3% to 14.6% and 11.8% to 12.5%, for B and A, respectively. The conclusion reached for Sample A is not changed by specifying different criteria for inclusion in the sample: In 1972 APA journals, women were not selected as editors as often as one would expect from their numbers as authors or as first authors.

Some Conclusions and a Suggested Index of Sexual Equality

There are several conclusions to be drawn from these data. The most general are those based on two samples of journals: Sample A, 11 journals in 1970–1972, and Sample B, APA journals in 1972:

1. Although there is variation from field to field, women are represented as authors of published research about as often as one would expect from their division membership in APA.

2. For Sample A, 5% of the editors are women, while 15% of the authors and 12% of the first authors are women. For Sample B, 7% of the editors are women, while 14% of the authors and

12% of the first authors are women. Women are not represented as editors as often as one would expect from their numbers as authors.

Some other conclusions are more tentative, being based on smaller samples of one or two journals:

3. For one journal (the *Journal of Experimental Psychology*) and two years (1961 and 1971), the percentage of citations to women authors is consistently about 11% for a period up to 15 years prior to the date at which an article is cited; this percentage corresponds closely to the percentage of women first authors for the journal. There was no trend, from 1961 to 1972, of increasing proportions of women authors in this journal, nor any trend of increasing citation rates for women authors. Neither relative age of women authors nor relative quality of women's research can account for the discrepancy between percentage of women editors and percentage of women authors for this journal.

4. There are some differences in publication patterns between men and women. Based on the full sample of journals, men are more likely than women to be first authors of published research. Based on a sample of two journals from 1965 to 1969, women are more likely than men to have published only one paper, whereas men are more likely than women to have published four or more papers, in a particular journal over a five-year period. The differences in publication patterns lead one to expect that the percentage of editors who are female will be somewhat less than the percentage of authors who are female. However, the magnitude of the discrepancy seems too great to be accounted for by these differences.

AN INDEX OF SEXUAL EQUALITY

To facilitate comparison between journals with differing percentages of women authors, an index can be constructed for each journal by comparing the obtained percentage of women editors with the percentage to be expected in the absence of sexual bias in the selection process. The percentage of women authors probably somewhat overestimates the expected value for editors, and the data are too fragmentary to permit a correction for rate of publication. However, a correction in the appropriate direction can be accomplished by taking percentage of first authors who are women as an estimate of the expected percentage of editors who are women. (This approximation gains plausibility from the

fact that the percentage of women authors corresponds closely to the percentage of women cited authors for at least one journal.) Then the ratio (*percentage women editors*)/(*percentage women first authors*) takes values from 0 to 1, with a value of 1 indicating complete equality of opportunity for women in editorial appointments (when the expected value exceeds the obtained value, presumably by chance, the index value is defined as 1). In 1970, for Sample A as a whole, this index of sexual equality is .37; for the individual journals, the median value is .35. In 1971, the index of sexual equality is .36 for Sample A as a whole; the median for individual journals is .36. In 1972, the index of sexual equality is .42 for Sample A as a whole; the median for individual journals is .36. There was little or no change in opportunity for women in Sample A from 1970 to 1972.

For Sample B (APA journals) in 1972, the index of sexual equality for the sample as a whole is .61; the median index of sexual equality for individual journals is .52. (The comparable figures for non-APA journals in Sample A for 1972 are .36 and .36.) APA journals currently exhibit less sexual bias in selection of editors than the other journals sampled, but they do not yet offer complete equality to women.

The present data suggest nothing about *how* such bias in the selection of editors might operate. White (1970) discussed the difficulties faced by women in becoming part of a professional "establishment." Perhaps women psychologists are less likely to be suggested or considered by colleagues for the post of editor for some of the reasons outlined by White and by Lewin and Duchan (1971): the reluctance of men to "sponsor" women professionally, or to engage in informal professional interactions with them; the tendency of men to doubt that women (but not men) can handle professional commitments without neglecting family commitments, or to question whether women (but not men) will be compatible with male colleagues.

The analyses presented here suggest that selection procedures for editors of two samples of psychological journals for 1970-1972 were not sex blind, and that, as a consequence, similar publication records for men and women had different outcomes. And it is a plausible conjecture that the higher probability that a male psychologist will receive the recognition of an editorial appointment also increases the probability that he will maintain a high publication rate. There are not enough women editors, not only from the standpoint of

women psychologists themselves, who must find the lack of recognition for professional achievement discouraging, but also from the standpoint of the profession, which ought to be concerned to maximize the productivity of all psychologists, not just the three quarters who are men.

New England Psychological Association

Proceedings of the Thirteenth Annual Meeting

BARBARA ROSS *Secretary-Treasurer*
University of Massachusetts at Boston

The Thirteenth Annual Meeting of the New England Psychological Association was held November 9-10, 1973, at the University of Massachusetts at Boston. There were 314 registrants.

The Steering Committee and Officers planned the program and selected the topics. Chairmen organized their respective sessions. Celia Moore, University of Massachusetts at Boston, served as Local Arrangements Chair; Mortimer H. Appley, University of Massachusetts at Amherst, as Elections Committee Chair; Robert C. Birney, Amherst College, as Student Liaison Officer; and Arthur M. Kaplan, University of Maine, as Program Coordinator.

Officers for 1973-1974 are: President, Mortimer H. Appley, University of Massachusetts at Amherst; President-elect, Robert C. Birney, Amherst College; Past President, Ethelyn H. Klatskin, Yale University Child Study Center; Secretary-Treasurer, Barbara Ross, University of Massachusetts at Boston. Newly elected members of the Steering Committee (1974-1976) are Zella Luria, Tufts University; Freda Rebelsky, Boston

University; and Seymour Wapner, Clark University.

All accredited institutions of higher learning in New England were again invited to nominate outstanding undergraduate junior or senior psychology majors for possible election as NEPA Undergraduate Fellows and Honorary Student Members. The students selected will be announced to members in the spring letter.

In addition to the traditional program format, Working Lunches were held on Saturday on a variety of topics, including a session for chairmen of psychology departments. A book exhibit was also available.

Ethelyn Klatskin, President, chaired the annual business meeting of the Association. Reports were heard from committee chairmen and the Secretary-Treasurer. Following the business meeting, the Donald G. Marquis Memorial Lecture, "A Century of Psychotherapy, Plus or Minus a Decade," was given by Roger Brown, Harvard University.

The Fourteenth Annual Meeting will be held November 15-16, 1974, and is tentatively scheduled at the University of Massachusetts at Boston.

PROGRAM

Paper Sessions

Peripheral Vision

JOHN L. KOBRICK, U.S. Army Research Institute of Environmental Medicine, Natick, Massachusetts, Chair

Effects of Environmental Stress Factors on Peripheral versus Central Visual Response. JOHN L. KOBRICK.

Overview of Problems in Peripheral Vision Research and Some Approaches. LEWIS O. HARVEY, Massachusetts School of Optometry, Boston.

Effects of Large Moving Fields: Peripheral versus Central Stimulation. RICHARD M. HELD, Massachusetts Institute of Technology.

Temporal Factors in Visual Processing. RUTH RUTSCHMANN, Queens College of the City University of New York.

New Pathways in Attribution Theory

WALTER SWAP, Tufts University, Chair

Attribution and Emotion. JUDITH RODIN, Yale University.
Cognitive Bases of Stereotyping Behavior. SHELLEY TAYLOR, Harvard University.

Attribution. LESLIE MCARTHUR, Brandeis University.

The Rights of Hospitalized People

GEORGE ALBEE, University of Vermont, Chair

Overview of a Dehumanizing System. GEORGE ALBEE.
The Hospitalized Person as Research Subject. STEVEN GOLDSTEIN, University of Vermont Medical Center.
The Impact of the Resident Rights Movement on Institutional Behavior Therapy Programs. BERNARD SAPER, Bangor Mental Health Institute and University of Maine, Orono.

Victimizing the Poor. WILLIAM RYAN, Boston College.

Recent Epidemiological Findings: Some Implications for Patients' Rights. LENORE K. MORRELL, Laboratory of Community Psychiatry, Harvard University.

Discussant:

MARJORIE BARNETT, Mental Patients Liberation Front, Boston, Massachusetts.

Maternal Behavior

J. S. ROSENBLATT, Institute of Animal Behavior, Rutgers University, Chair

A Theory of Maternal Behavior Derived from Animal Studies. J. S. ROSENBLATT.

Synchrony in the Early Mother-Infant Relationship. EVELYN THOMAN, Biobehavioral Sciences, University of Connecticut.

Clinical and Theoretical Aspects of Early Mother-Infant Interaction. KENNETH ROBSON, Tufts New England Medical Center.

Person-Environment Assessment and Its Implications for Community Psychology: Theory, Research, Practice, Training

STUART E. GOLANN, University of Massachusetts at Amherst, Chair

Conceptual Approaches and Empirical Data on Person-Environment Assessment: A Current Summation. HAROLD L. RAUSCH, University of Massachusetts at Amherst.

Assessment of Individuals in a School Setting: An Ecological Conception of Psychological Evaluations. EDISON J. TRICKETT, Department of Psychology and Institution for Social and Policy Studies, Yale University.

Taking Ourselves Seriously: Implications for Training. DAVID M. TODD, University of Massachusetts at Amherst.

Discussant:

IRA GOLDENBERG, Harvard University.

Cognitions, Intervention, and Public Policy

ERNESTO POLLITT, Growth and Development, Nutrition and Food Science, Massachusetts Institute of Technology, Chair

Conceptual Issues Concerning Intervention. CHARLES P. GERSHENSON, Florence Heller Graduate School for Advanced Studies in Social Welfare, Brandeis University.

Child Development and Public Policy: Intervention by Action and Inaction. FREDA REBELSKY, Boston University.

The Nature of Cognitive Development and the Issue of Intervention. JEROME KAGAN, Harvard University.

Working Lunches

Chairmen of Psychology Departments. RICHARD LOUETTIT, University of Massachusetts at Amherst, Chair.

Behavior Modification. PETER WISH, Framingham State College, Framingham, Massachusetts, Discussion Leader.

Counseling Psychology. Division 17 of APA, Conversation Hour. J. ALFRED SOUTHWORTH, University of Massachusetts at Amherst, Discussion Leader.

Historical Development of Psycholinguistics. ARTHUR BLUMENTHAL, Harvard University.

Human Ethology: Observational Studies of Human Behavior. GEORGE MICHEL, Boston University.

Massachusetts Psychological Center. HERBERT J. HOFFMAN, Discussion Leader.

The Biomedical Model in the History of Psychology. OTTO MARX, Boston University School of Medicine, Discussion Leader.

Models of Man: Deception, Role Playing, Obedience. DONALD MILON, University of Massachusetts at Boston.

Psychoeducational Programs. RONALD L. SEIFER, Saratoga County Mental Health Center, Discussion Leader.

Psychological Tests, Occupational Selections, and Equal Employment Opportunity Commission Guidelines. PAUL COSTA, University of Massachusetts at Boston, Discussion Leader.

Undergraduate Students in Social Service Agencies. BERTON FLIEGEL, University of Massachusetts at Boston, Action Program, Discussion Leader.

Hospitalized Children. BARBARA POPPER, Children in Hospitals, Boston, Massachusetts, Discussion Leader.

Teaching Psychology in Community Colleges and High Schools. DANIEL VAN LEUVAN, Nichols College, Dudley, Massachusetts, Discussion Leader.

The Use of Surveys in Social Policy Evaluation. LAURENCE G. BRANCH, Survey Research Program, University of Massachusetts at Boston, Discussion Leader.

Representation of Information in Human Problem Solving. STEVEN SCHWARTZ, University of Massachusetts at Boston, Discussion Leader.

Presidential Address

In lieu of the Presidential Address, Dr. Klatskin arranged a special lecture in honor of Donald G. Marquis, Past President of NEPA and an outstanding scholar in the field of psychology. The Donald G. Marquis Memorial Lecture given by ROGER BROWN, Harvard University, was entitled "A Century of Psychotherapy, Plus or Minus a Decade."

What Is the Source of the Fullerton-Cattell "Principle"?

While working on a commissioned chapter for a forthcoming handbook, I became intrigued by a rather common tendency of writers about psychophysics to attribute to Fullerton and Cattell (1892) the statement "Equally often noticed differences are equal unless always or never noticed" (cf. Bock & Jones, 1968, p. 24, who give a page reference; Guilford, 1954, p. 40; or Torgerson, 1958, who stated that the work of Fullerton and Cattell led to a statement similar to the quotation, p. 155). I can find no such statement in Fullerton and Cattell, and to my impression, the whole spirit of their monograph is quite the contrary. In fact, Cattell (1893) concluded a discussion of psychophysics with the following: "I conclude, consequently, that we cannot measure the intensity of sensation and its relation to the energy of the stimulus either by determining the error of observation or by estimating amounts of difference . . ."

As far as I can discover, and I should like to be corrected if I am wrong, the first attribution to Fullerton and Cattell was by Thurstone (1932) who had, interestingly, already demolished the "principle" without attribution (Thurstone, 1927). As a matter of fact, the one reference to Thorndike (1910) in the 1927 publication probably gives the correct clue. (Actually, this is an "implied" reference. The exact citation is not given.) In reporting his scale of handwriting, Thorndike (pp. 5-6) stated explicitly the assumption attacked by Thurstone. This was the first statement of the point that I can find, although it seems obvious that the idea was "in the air." Perhaps until an earlier reference is found, we should give credit, if it be

credit, where it is due, and refer to "Thorndike's Principle"!

On the Diversification of Graduate Study in Psychology

Having a little free time, I went through *Graduate Study in Psychology 1974-75* (APA, 1973) and, as an exercise in what I now realize was futility, attempted to categorize the various listings as to degree areas cited by each school. I made no differentiation between master's and

doctoral programs, and what to my wondering eyes appeared were over 75 different fields of study in which a graduate student in psychology could specialize. I recognize that this is an age of specialization, but this finding was overwhelming. If psychology continues in this manner, it would seem obvious that we are going to become so specialized that those of us in the academic area will wind up being able to teach one course and no more, and those in the professional areas will be able to carry out only one function.

As a professional, I am confused when I read through the handbook and find so many different areas of specialization, and I can only imagine the feelings of a potential student. I realize that I am exaggerating to some extent, but I sincerely believe that we have a problem that requires some solution.

The Artifact as Artifact: A Reply to Epstein et al.

Recent research (Epstein, Suedfeld, & Silverstein, 1973) attempted to discover the parameters implicit in the subject-experimenter contract and to assess the degree to which violation of this implicit contract affects experimental performance. The study was conducted in three stages. The first two stages provided important information on the substance of subjects' expectations about psychological experimentation. The third stage studied the effect on task performance of experimenter lateness, a behavior considered by subjects as both undesirable and in-

appropriate. The intention was to contribute to the literature on experimental artifacts (e.g., Barber, 1972; Rosenthal, 1966). However, various statistical and interpretative oversights render the conclusions of this third stage the true artifact.

In each of two experimental sessions, subjects performed a modified WAIS digit-symbol task for four 2.5-minute blocks. In Session 2, the 40 subjects were divided randomly into four groups: One group performed the task as scheduled (no lateness—NL); a second group performed after an imposed 20-minute rest period—the experimenter was not late (waiting control—WC); the third group was forced to wait 20 minutes because of the experimenter's "justified lateness" (JL); and the fourth group was forced to wait 20 minutes when the experimenter was late without explanation (unjustified lateness—UL).

According to the experimental hypothesis, breach of the experimental contract, culpable lateness, should be reflected in the performance differences between the JL and UL groups. *In fact, no such differences were found.* On the basis of a questionnaire returned by the subjects after the experiment, however, the UL group was divided into those who reported that the experimenter had been late (UL-A, $N = 5$) and those who did not (UL-N, $N = 5$). (Note that failure to report lateness as an inappropriate event does not mean that subjects were not aware of the lateness, as the authors assert. These subjects might not have perceived experimenter lateness as inappropriate or might simply have ignored it.) Subsequent analysis of the performance data uncovered a significant "decrement" for the UL-A group. This led to the authors' conclusion that performance was affected by perceived culpable lateness and that care must be taken to avoid unwanted interactions between subjects' expectations and "extraneous" experimenter behavior in the collection of experimental data. Furthermore, it is claimed that subjects in the UL-A group reported significantly

more dissatisfaction toward psychological experimentation than did the NL control group. The justification for these conclusions must be scrutinized carefully.

On Reported Dissatisfaction Differences

1. The UL-A group is seen as possibly brighter, more committed, and more observant than the other groups (Epstein et al., 1973, p. 220), so the factors underlying the satisfaction difference are unclear. *No* comparison using the present data can support the authors' contention about reported dissatisfaction: the UL-A subjects were chosen on the basis of a postmanipulation observation. To conclude that they were less satisfied with psychological experimentation after the manipulation, it is necessary to know what their attitudes were *prior* to the manipulation to infer that it had an effect. The use of this group renders untenable any assumption about random assignment and any conclusions drawn from it (Campbell & Stanley, 1966; Glass & Stanley, 1970).

2. The use of the t test to compare the satisfaction of NL and UL-A groups is plainly inappropriate. In the Methods section of the original article, three contrasts were mentioned explicitly for the performance data. It would seem that these contrasts are equally important in analyzing reported dissatisfaction. For example, differences between the NL and WL groups could be attributable to the experience of waiting *per se*. Subjects who value their time may well resent unnecessary delay. Consequently, an analysis of variance and computation of multiple contrasts are required to test the significance of any comparison. Indeed, under the present circumstances, where 10 pairwise t tests are possible, the probability that at least one will be significant at the .05 level is .40. Granted the loss of power with the appropriate test and the weak significance of the reported t value, the correct test might not have shown a reliable difference.

It is not unlikely that any "sensitization" (Epstein et al., 1973, p. 220) is more apparent than real.

On Performance Decrement

There is equivalent reason to be skeptical about the "performance decrement."

1. It is not clear why Epstein et al. were entitled to choose an ad hoc control group of the six highest scoring Session 1 performers to demonstrate that the UL-A performance decrement in Session 2 did not derive from a ceiling effect. The choice of this group represents yet another after-the-fact decision, impermissible in a rigorous statistical design without appropriate safeguards. Conclusions based on their performance are unsupported at best. Furthermore, Epstein and his colleagues did not demonstrate the comparability of this control group to the UL-A group. With so few subjects, a real difference in ability might not be caught by a statistical test on the Session 1 data. (It is difficult to prove the null hypothesis of no differences.) The authors summarized their conclusions but reported no data, yet their conclusions rested more strongly on the performance of those six subjects than on the group data they did report. Since subjects were initially assigned to three well-defined control groups, it is to the performance of these groups that the authors must appeal to support their conclusions, or else collect additional data.

2. A plot of the Session 2 group means reveals that the "decrement" in performance derives from the score in Block 4. Had this score, which is still higher than that of any other group in the *entire* study, been more in line with the other three UL-A scores, it is not likely that any singular decrement would have been found. Though it is agreed that the Block 4 mean for the UL-A group represents a decrease, it is not clear that it derives from the experimental manipulation. The authors offered no reason why the decrement does not appear until 7.5 minutes after

the start of Session 2. An alternative explanation for these phenomena, which fits the data at least as well as the one offered by Epstein and his colleagues, is not that overt or covert sabotage takes place, but that the UL-A subjects simply tire. In absolute terms, 150 symbols per 2.5-minute block is rather astounding. This is one symbol per second, the maximum rate coded for the WAIS subtest itself (Wechsler, 1955; in fairness, WAIS subjects are not allowed to practice, but they are only required to perform for 1.5 minutes, not 10). Nevertheless, the UL-A subjects, who supposedly are "retaliating," continue to work at this blistering pace for 7.5 minutes. It is not unreasonable to propose that 7.5 minutes of high-level cognitive functioning at a boring and repetitive task would induce fatigue and a corresponding decrease in performance rate. The "fourth-quarter fade" need not be documented for any athletic coach or long-suffering fan. The other subjects, operating at a more comfortable level, would not be expected to show a similar "fade."

3. The Block 4 UL-A score may be simply a random fluctuation. Without a replication, it need not be considered representative of the "true" Block 4 score. When a conclusion which has potentially far-reaching implications for the conduct of psychological research depends on the performance of five subjects for 2.5 minutes, it should be examined closely to rule out alternative explanations. No such disqualification is justified on the basis of the data presented.

4. The sole support for the existence of a performance decrement is provided by the covariance analysis. The authors referred to the "examination of the data" to determine that the UL-A group was unique in displaying a performance decrement. Did they examine the raw means? If not, why are the covariate adjusted means not presented? Without knowledge of these means, it is difficult to make dependable inferences. Was a statistical

test performed to support the existence of a unique UL-A decrement? If so, why was it not reported? (It is possible that the covariance analysis for the Session 2 scores was performed only on the UL-A and UL-N groups. If so, it is not legitimate to conclude that the UL-A group is unique in showing a performance decrement. There would be no assurance that the UL-A group is significantly different from the NL, WC, and JL groups.) The meaning of these analyses cannot be discovered from the reported results.

5. The authors seemed to neglect entirely (in drawing their conclusion about performance decrement) that the UL-A and UL-N groups are essentially drawn from different populations, as demonstrated by performance differences at the .01 level for Session 1 scores. Meehl (1969, expanded in 1970) and Lord (1969) have noted the difficulties in attempting to correct for these differences by covariance analysis. Especially when the underlying variables responsible for high UL-A performance (e.g., IQ, motor skill, commitment) are the variables which determine assignment to the UL-A group, the effect of the experimental manipulation and the effect of these uncontrolled nuisance variables must remain confounded. The ascription of any differences to perceived culpable lateness is at the least overzealous.

Although it may be demonstrable that violation of the implicit contract between experimenter and subject can vitiate the results of psychological experimentation, such a demonstration is not provided by the research considered here.

Ecological Knowledge and Perception of Environmental Modifiability

Maloney and Ward (1973) presented an objective scale for the measurement of ecological attitudes and knowledge. I would like to elaborate on two specific points made in their article: (a) Maloney and Ward found that their measure of environmental knowledge did not correlate significantly with actual commitment. These investigators attempted to explain this lack of a relationship by reasoning that the subject matter of ecology is difficult to understand, and thus it is difficult to develop an ecological knowledge scale with high probability or "easy" items. (b) Maloney and Ward stated that their subjects' high verbal commitment to ecological issues "should make fertile soil for the modification of ecologically relevant behaviors [pp. 585-586]."

My research examining correlates of citizen involvement in voluntary,

antipollution activities indicates that (a) an ecological knowledge scale providing a wide range of item difficulty has been developed and (b) the changing of environmental behaviors based on certain attitudes may be more complex than is suggested in the Maloney and Ward article. I will briefly describe a study in which I hypothesized that people active in antipollution activities would score higher on a test of ecological knowledge and would perceive to a greater extent that something positive could be done to clean up the environment than those not so involved.

The subjects were 96 male and female adults in a southwestern metropolitan area. One third of the subjects were selected randomly from the membership list of a local antipollution group (members). Another third were selected from those people who had been sent a letter of notification of the group but did not join, and the final third had not been notified of the group (nonmembers). Subjects were matched for sex and socioeconomic status (occupation and residence).

As part of a larger study, a series of scales were administered to each subject during an individual interview session. Included with the measures were an ecological knowledge test, an attitude scale to measure perceptions of the degree to which pollution could be lessened (modified), and an involvement activities checklist. The knowledge test was the 27-item, multiple-choice Test of the National Environment, designed and used by the Columbia Broadcasting System, Inc., in a national survey. Each question answered correctly receives 4 points (range 0-108). The Environmental Modifiability Test constructed for the study (Levenson, 1973) was patterned after items loading on a system modifiability factor found in research dealing with the motivational dynamics

of black youths (Gurin, Gurin, Lao, & Beattie, 1969). A high score on the Modifiability Test indicates that the subject feels that pollution can be lessened (range 0-36). The Involvement Checklist is a self-report measure consisting of 15 activities. The subject checks those things he has done to express his concern over environmental problems (range, 0-15).

As expected, results indicated that the Test of the National Environment was sensitive to group differences (members: $M = 83.6$, $SD = 8.9$; nonmembers: $M = 71.6$, $SD = 13.2$; $F = 18.43$, $p < .001$), and scores on the knowledge test were significantly correlated with the number of antipollution activities checked by the subjects ($r = .54$, $p < .01$).

Contrary to the second hypothesis, however, those who were involved in nine or more antipollution activities scored significantly lower on the Environmental Modifiability Test ($M = 23.6$, $SD = 6.7$) than those who were involved in four or fewer activities ($M = 27.5$, $SD = 5.2$; $F = 4.01$, $p < .05$). Similar results were found for members versus nonmembers, the latter group being more optimistic about the possibilities of cleaning up the environment (Levenson, 1973).

Two reasons are proposed to explain why those who were less involved perceived more chances for eliminating pollution. First, the items on the Modifiability Test focus on the power of society to cure environmental problems using technological means. This emphasis is consistent with a prevalent value orientation in the United States—a belief in man's dominance over nature (Kluckhohn & Strodtbeck, 1961). During the interview sessions, however, many of those who were involved in antipollution efforts voiced quite opposite views, expressing the belief that man must learn to live in harmony with the environment.

Second, the items on the Modifiability Test tend to accentuate the ease with which pollution can be lessened. Yet those who were the most involved maintained that their efforts were part of a very difficult and complex undertaking which would eventually result in fundamental changes in economic and social values. It appears, then, that the involved subjects' lower scores on the Environmental Modifiability Test should be interpreted as indicating disapproval of additional technological interference and disagreement with simplistic perceptions of environmental issues.

From these correlational findings, causation cannot be ascertained. However, one may speculate that an optimistic assessment of the chances of eliminating environmental degradation, coupled with high verbal commitment to ecological issues, may in fact encourage a lack of action. If such is the case, then the numerous antipollution campaigns, emphasizing the ease with which the environment can be restored, may result in the undesired effect of less citizen involvement in ecological efforts.

Announcements

New Members and Associates

The name of *Bruce W. Jorgensen* should be added to the list of new Members elected to initial membership in the APA, as of January 1, 1974, making the new total 2,907 (see February issue, pp. 135-147, for original lists).

American Board of Professional Psychology

The *American Board of Professional Psychology*, during the period December 12, 1973, to February 21, 1974, awarded its diploma in the specialities of Clinical and School Psychology to the following:

CLINICAL

Melba Hurd Duncan
Elizabeth Ann Kolin
Selwyn Lederman
Samuel Roll
Wolfgang Schwarz

SCHOOL

Barbara Ruth Slater

In the February issue (p. 153), ABPP listed *Bruce T. Saunders* as a newly awarded Clinical Diplomate. It should have read Diplomate in School Psychology.

Fellowships; Predoctoral and Postdoctoral Programs

College of Law and the Psychology Department of the University of Nebraska—Lincoln: Announce the law-psychology graduate studies program leading to both a regular law degree, the Juris Doctor, and a PhD in psychology. This program will typically take a student five years to complete both degrees. The student may take his PhD in any of four areas: general-experimental, social-personality, community-clinical, or psycholegal studies. For further information contact Bruce Dennis Sales, 209 Burnett Hall, University of Nebraska—Lincoln, Lincoln, Nebraska 68508.

Division of Psychology, Department of Psychiatry, University of Rochester Medical Center: Now accepting applications for postdoctoral fellowships in psychology with specializations in (a) adult clinical psychology, (b) child clinical psychology, and (c) community psychology. For further information and application forms write to Robert H. Goldstein, Director of Clinical Training,

Division of Psychology, University of Rochester, Medical Center, 260 Crittenden Boulevard, Rochester, New York 14642.

San Bernardino County Department of Mental Health: Now accepting applications for 20 full- and half-time, one-year clinical and counseling, pre- and postdoctoral internships and residencies beginning July 1, 1974. Humanistic, crisis intervention, multidisciplinary community mental health system. Central Unit with 225 employees, contractual affiliation with 22 local community agencies and clinics throughout the county. Individually designed clinical experiences, training seminars, supervision. For information and applications write to Stephen B. Lawrence, Chief Psychologist, Director Psychology Training, San Bernardino County Department of Mental Health, 780 East Gilbert Street, San Bernardino, California 92404.

Society for Research in Child Development: Interdisciplinary research institute from June 17 to July 12, 1974, at the University of Delaware on the topic of reading and child development. Emphasis will be on research hypotheses and strategies that will contribute to an understanding of the reading process. Applications are invited from advanced doctoral students and young faculty in the behavioral sciences, education, and pediatrics. Travel and living expense support provided. Applicants should contact Frank B. Murray, College of Education, University of Delaware, Newark, Delaware 19711.

Sugar Bowl . . . Superdome, finished or unfinished . . . topless dancers . . . voo-doo.

And that is where the 1974 Convention of the American Psychological Association will be held. The dates of the Convention are **August 30 through September 3**. While August is not the ideal time to be in New Orleans, the attractions of the city should compensate for the heat and humidity. Meetings are scheduled in the Fairmont Hotel, the International Hotel, the Marriott Hotel, the Monteleone Hotel, the Royal Orleans Hotel, and the Rivergate Exhibition Center. The bulk of the Convention program is scheduled between 9:00 a.m. and 6:00 p.m. during the five days of the meeting. Because hotels are fairly close to one another, APA is not planning to run a shuttle bus among the hotels. Public transportation buses run up and down Canal Street every few minutes at a cost of 15 cents per person.

Canal Street, New Orleans' main thoroughfare, separates the French Quarter from the business district and uptown area of the city. There are historical

sights, shops, nightclubs, and restaurants within the French Quarter. In order to sample the cuisine in local restaurants it would be wise to make reservations for all meals. A handy reference on inexpensive and good restaurants is *The New Orleans Underground Gourmet* by Richard H. Collin.

Transportation from the New Orleans International Airport to the downtown area is available by taxicab or limousine. It takes about 30 minutes to make the trip. The taxicab fare is approximately \$9 plus tip for one to three persons; there is an additional charge of \$3 per person for more than three. Limousine service is available directly to the hotels at \$3 per person. Public transportation is also available from the airport for a fare of 35 cents, but it may be necessary to transfer to another bus within the city in order to get directly to your hotel. See you in New Orleans!

Housing

In cooperation with APA, all of the hotels have set aside, at guaranteed rates, substantial blocks of rooms. These hotels have guaranteed rates for the Convention only when registration is made through the APA Housing Bureau on the official Hotel Reservation Form. Also, these rates are guaranteed only when the Advance Registration Form and Hotel Reservation Form are returned *prior to August 1, 1974*. After August 1, every effort will be made to assign rooms at the guaranteed rate, but such assignments cannot be certain, and it is quite unlikely that late requests can be honored.

Members should also bear in mind that with the large number of rooms used, some members may not be assigned a room in the specific hotel they requested nor the type of room at the rate requested. It is advisable to return the Advance Registration Form and the Hotel Reservation Form as early as possible. These forms appear at the end of this section.

All housing forms are sent from the Central Office to the New Orleans Convention Bureau for room assignments. We anticipate a three- to four-week lag between receipt of request in the APA office and your receiving confirmation from the hotel. If after four weeks you have not heard from New Orleans, please contact di-

rectly the New Orleans Convention Bureau, 334 Royal Street, New Orleans, Louisiana 70130.

Wheelchair Accessibility

To facilitate making hotel reservations for those people concerned with wheelchair accessibility, Division 22, the Division of Rehabilitation Psychology, compiled the following information on the accessibility of some of the Convention hotels. Wherever possible, the information has been corroborated by site visits made by knowledgeable persons. Detailed information about the accessibility of various churches, restaurants, museums, and stores may be obtained by writing for a free copy of *Guide to New Orleans for the Handicapped* from Louisiana Chapter, National Society for Crippled Children and Adults, Inc., 843 Carondelet Street, New Orleans, Louisiana 70130.

Rivergate Exhibition Center

Main entrance: Accessible
Restrooms: Accessible
No sleeping rooms

International Hotel

Main entrance and elevators: Accessible
Public restrooms: Accessible
Sleeping rooms: Two meet accessibility requirements and must be requested.

Monteleone Hotel

Garage entrance and three elevators: Accessible
Public restrooms: Accessible
Sleeping rooms: Hotel has 56 accessible sleeping rooms which must be specifically requested. They are rooms on the fifth floor in the following series: 53, 56, 57, 58, 63, and 69.

Fairmont Hotel

One of the main entrances to the hotel is ramped.
Public restrooms: Women's—accessible
Men's—inaccessible
Sleeping rooms: Inaccessible

Royal Orleans Hotel

Main entrance: Assistance available to negotiate the steep ramped entrance from garage and stair main entrance.
Elevators: Accessible
Public restrooms: Accessible
Sleeping rooms: Inaccessible

Marriott Hotel

Main entrance: Accessible
Elevators: Accessible
Public restrooms: Inaccessible
Sleeping rooms: Inaccessible

Royal Sonesta Hotel

Main entrance: Accessible
Elevators: Accessible
Public restrooms: Inaccessible
Sleeping rooms: Inaccessible

Persons requesting wheelchair-accessible accommodations should check the appropriate box on the Hotel Reservation Form as well as indicate the hotel and type of accommodation requested.

Registration

Convention attendees are urged to register for the meeting in advance. Not only will advance registration assist APA in planning for the meeting, but advance registration represents a saving to the registrants as well as the opportunity to obtain desired hotel space and rates. At its meeting on January 18–20, 1974, the APA Council of Representatives approved the following registration fees for the 1974 Convention:

For those registering in advance (prior to August 1, 1974):

\$30—Nonmember
\$20—APA Member, Fellow, Associate, Foreign Affiliate,
High School Teacher Affiliate

For those registering on-site in New Orleans:

\$35—Nonmember
\$25—APA Member, Fellow, Associate, Foreign Affiliate,
High School Teacher Affiliate

23. Saint Louis Hotel
24. Tamanaca (Best Western) Downtown Motel
25. Thunderbird (Quality Inn)
26. Vieux Carre Motor Lodge

Students and other authorized exemptions from these fees appear on the Advance Registration Form.

The convention badge, with name and institutional affiliation, will be mailed in advance of the Convention to those who preregister. Advance registrants will need only to obtain a badge holder at the APA registration area in New Orleans to complete the procedure—thus avoiding possible delays.

Complete member and nonmember registration facilities will be maintained at three locations—the Fairmont Hotel, the Marriott Hotel, and the Rivergate Exhibition Center—according to the following schedule:

Thursday, August 29, 3:00 p.m. to 9:00 p.m.

Friday, August 30, 8:30 a.m. to 5:30 p.m.

Saturday, August 31, 8:30 a.m. to 5:30 p.m.

From Sunday, September 1 through Tuesday, September 3, registration facilities will be available only at the Rivergate Exhibition Center. Hours will be 8:30 a.m. to 5:30 p.m. on Sunday and Monday; 8:30 a.m. to 12 noon on Tuesday.

Placement

The APA Convention Placement Office will be located in the Rivergate-South Hall. Hours will be from 9:00 a.m. to 5:00 p.m., August 30–September 3, except 1:00 p.m. closing day. Fees required are as follows:

Applicants—\$2 for reproducing (1) availability information. \$3 for use of Convention Placement facilities includes a copy of the *Position Openings Bulletin*. (Nonmembers will be charged \$20 for use of Convention Placement facilities.) July 19, 1974, is the deadline for applicant listing. Appropriate fee must accompany listing.

Employers—\$5 for reproducing (1) Job Description. \$10 for use of Convention Placement facilities includes a copy of the *Availability Notices Placement Bulletin*. July 26, 1974, is the deadline for employer listing. Appropriate fee must accompany listing.

Employers: Please note the addition of the GENERAL OPENINGS category to be used by organizations hav-

ing widespread needs for psychologists who may be recruited through a central office.

Prelisting in the more widely distributed printed booklet is encouraged, but Xerox forms will be available for on-site listing. The forms, accompanied by the appropriate listing fee, must be received by the date indicated above. Please do not include the Convention Placement facilities fee which will be collected ONLY when you register at the Placement Office. After the above date, Xerox forms will be available for listing, and requests should be directed to the address below.

A complete set of applicant availabilities will be available to employers: \$15 for each category—please indicate choice. After the Convention, order from the Convention Placement Office, American Psychological Association, 1200 Seventeenth Street, N.W., Washington, D.C. 20036.

Mail orders for the printed *Availability Notices Placement Bulletin* and the *Position Openings Bulletin* are \$1.50 per copy (available August 7). Your check (no billing) may be sent to the above address.

Convention Personnel

You may wish to contact one or more of these people before or during the Convention:

Board of Convention Affairs: Carl N. Zimet, Division of Psychology, University of Colorado School of Medicine, Denver, Colorado 80220.

Convention Manager: Theodore G. Driscoll, Jr., Driscoll and Associates, 7109 Masters Drive, Potomac, Maryland 20854.

Assistant for Convention Management: Candy Won, American Psychological Association, 1200 Seventeenth Street, N.W., Washington, D.C. 20036.

Convention Placement Office: Jim Beauter, American Psychological Association, 1200 Seventeenth Street, N.W., Washington, D.C. 20036.

Convention Child Care Service

Provision has been made for a professional child care service during the 1974 Convention. CON-SERV has been engaged and will offer an extensive program.

Parents desiring to use child care facilities must preregister no later than July 15, 1974. To preregister, complete the form at the bottom of this page. Please note that upon filing of the preregistration form and payment of the advance deposit as indicated on the form, CON-SERV will provide complete detailed information about the services offered and final registration materials necessary to plan for your children's comfort and safety. If for any reason your plans change, the deposit will be refunded in full if CON-SERV is notified of cancellation by August 10.

Some of the essential features of this service, as planned, are indicated below:

- The facility will be located in Braniff Place Hotel and will be open from 8:00 a.m. to 6:30 p.m., August 30-September 3, 1974. While the cost will be about \$1.50 per hour per child, APA will subsidize \$.75 of this cost. Hence, the cost to parents during the daytime will be \$.75 per hour per child.

- If there is sufficient need, the facility will remain open after 6:30 p.m. until 12 midnight to accommodate

parents who may wish to leave their children in the facility during evening hours. The parents will bear the full cost during these hours. If the need for evening child care does not justify keeping the facility open after 6:30 p.m., personnel at the facility will make every effort to help individual parents locate qualified babysitters to stay with children in their hotel rooms for those who might need this service. In any event, every effort will be made by CON-SERV to assist parents with evening child care arrangements.

- During the regular daytime hours, a variety of optional tours will also be offered at modest cost to parents. APA will subsidize part of the cost to the extent of \$.75 per hour per child as though the child were in the facility.

- In order to evaluate the child care services at past conventions, the Task Force on Convention Child Care would like you to answer the following questions:

(a) What is your general reaction to past child care facilities? (b) What was the least-liked aspect of past facilities? (c) What was the most-liked aspect of past facilities? (d) What was needed and not provided in past facilities? Please attach your answers to the preregistration form.

Preregistration Form: Child Care Service—APA Convention New Orleans, Louisiana, August 30-September 3, 1974

Preregistration form must be returned no later than July 15, 1974.

Name of Parent or Guardian: _____

Street Address: _____

City, State, Zip: _____

Name(s) of children to be registered in the child care facility:

Age

Name

_____	_____
_____	_____
_____	_____

If your child has a specific problem or handicap that we should be aware of, that is, speech impediment, retardation, epilepsy, etc., please let us know so that we may make the necessary provisions. _____

Please check this box if you are interested in tour information for your child ☐

Signature of Parent or Guardian

Please return this form to Ms. Diane Snow, Con-serv, 1318 Arabella Street, New Orleans, Louisiana 70115, and enclose a check in the amount of \$7.50 for one child or \$15.00 for two or more children as listed above. Make checks payable to "Con-serv." Indicate amount enclosed: _____

NOTE: This is only your preregistration form. Upon receipt of this form you will be furnished complete registration materials.

Please read and these fees are only applicable for advance registration prior to August 1, 1974. After that date advance registration cards received in the APA Central Office will be returned and those wishing to register will have to do so onsite in New Orleans. If possible use this card rather than photocopied forms. Use another card for additional persons who wish to register. Additional cards can be obtained in any issue of the *American Psychologist* from April through July.

PLEASE COMPLETE BOTH SIDES OF THIS FORM

Convention attendees are urged to register for the meeting in advance. Not only will advance registration assist APA in planning for the meeting but advance registration represents a saving to the registrant. At its January 18-20, 1974, meeting the APA Council of Representatives approved the following registration fees for the 1974 Convention:

For Those Registering in Advance Prior to August 1, 1974:

\$30 Nonmember \$20 APA Member, Fellow, Associate, Foreign Affiliate, High School Teacher Affiliate

For Those Registering On-Site in New Orleans:

\$35 Nonmember \$25 APA Member, Fellow, Associate, Foreign Affiliate, High School Teacher Affiliate

Send completed form and check for registration fee to:

American Psychological Association
1200 17th Street, N.W., Room 601
Washington, D. C. 20036

Make checks payable to APA.

List of divisions for Question 1 on registration form:

- 1 - General, 2 - Teaching, 3 - Experimental, 5 - Evaluation and Measurement, 6 - Physiological and Comparative, 7 - Developmental, 8 - Social and Personality, 9 - SPSSI, 10 - Psychology and the Arts, 12 - Clinical, 13 - Consulting, 14 - Industrial, 15 - Educational, 16 - School, 17 - Counseling, 18 - Public Service, 19 - Military, 20 - Adult Development and Aging, 21 - Engineering, 22 - Rehabilitation, 23 - Consumer, 24 - Philosophical, 25 - Experimental Analysis of Behavior, 26 - History of Psychology, 27 - Community, 28 - Psychopharmacology, 29 - Psychotherapy, 30 - Hypnosis, 31 - State Psychological Association Affairs, 32 - Humanistic, 33 - Mental Retardation, 34 - Population, 35 - Psychology of Women.

Please fill out this form in COMPLETE detail, particularly ARRIVAL and DEPARTURE dates and type of ACCOMMODATIONS.

SEND APPLICATION AS SOON AS POSSIBLE to address shown at bottom of page to insure desired accommodations at convention rates. DEADLINE: August 1, 1974.

Male Homosexuals Their Problems and Adaptations

MARTIN S. WEINBERG and COLIN J. WILLIAMS, both of the Institute for Sex Research of Indiana University. The authors examine the problems and adaptations of homosexuals in the U. S., Denmark, and Holland with respect to society's institutions, values and expectations. Drawing on the experiences and feelings of 2,437 homosexuals, they discredit old stereotypes and present positive proposals for alleviating the problems the homosexual faces. "An important study, careful in its conclusions and with significant implications about the effect of societal reactions on the lives and feelings of homosexuals. . . . A substantial contribution."—Judd Marmor, M.D., former Vice President, The American Psychiatric Association

Spring 1974 322 pp. illus. \$10.95

Nonverbal Communication Readings with Commentary

Edited by SHIRLEY WEITZ, The Graduate Faculty, New School for Social Research. This volume presents twenty-two papers on five areas of nonverbal communication: facial expression and visual interaction, paralanguage, body movement and gestures, spatial behavior, and multichannel communication. The selections reflect all the contemporary perspectives including those of Birdwhistell, Dittmann, Elbl-Eibesfeldt, Ekman, Exline, Hall, Kendon, Mehrabian, Scheflen, and Sommer, among others. Each section is preceded by the editor's introduction which discusses significant theoretical and empirical directions in each area and the rationale for the selection of articles.

Spring 1974 368 pp. cloth \$10.00 paper \$4.95

Children and Adolescents Interpretive Essays on Jean Piaget Second Edition

DAVID ELKIND, University of Rochester. In his interpretive essays, David Elkind provides an introduction to Piaget's work and some of the ways in which his theories can be applied in child rearing and education. For this edition he has added two chapters and updated the chapter on reading. The first looks at Piaget's many investigations into children's time conceptions including a study of what they think about aging and age relations. The second new chapter covers five common misunderstandings about how children learn.

1974 208 pp. cloth \$6.95 paper \$2.95

Sight and Mind An Introduction to Visual Perception

LLOYD KAUFMAN, New York University. "This is a remarkable book. It is both broad and deep, a combination of qualities seldom achieved; it is a textbook of ideas as well as a source of necessary detail. It represents most of the concerns of most perception psychologists, yet it is highly personal and informed by Lloyd Kaufman's own opinions, solutions, and theories; it presents highly current research and research issues but it does so in the context of persistent classical problems."—Julian Hochberg, Columbia University

1974 560 pp. 258 illus. \$14.95

The Psychologists Volume II

Edited by T. S. KRAWIEC, Skidmore College. These autobiographical essays reflect the personality, outlook, ideals, and background of several noted contemporary psychologists as they each describe their work. Contributors include: Heinz Ansbacher, Josef Brožek, Raymond B. Cattell, J. McVicker Hunt, Arthur R. Jensen, Howard H. Kendler, Robert Ward Leeper, Gardner Murphy, Charles E. Osgood, Carl Pfaffmann, and Morris S. Viteles.

CONCEPTUAL LEARNING AND DEVELOPMENT

A Cognitive View

by HERBERT J. KLAUSMEIER,
ELIZABETH SCHWENN GHATALA and
DOROTHY A. FRAYER

CONTENTS: Toward a Theory of Conceptual Learning and Development. Attending and Discriminating. Remembering Stimulus Information. Generalizing and Higher-Order Operations. Language and Concept Attainment. Using Attained Concepts. Conditions of Concept Attainment. Validating the Levels of Concept Attainment. Application of the Model.

1974, 296 pp., \$15.00/£7.00

SENSORY PROCESSES: THE NEW PSYCHOPHYSICS

by LAWRENCE E. MARKS

CONTENTS: Introduction to Sensory Scaling. The Magnitude Estimation Experiment. Sensory Magnitude and the Sensitivity of Sensory Systems. Temporal Factors in Sensation. Spatial Factors in Sensation. Qualitative and Hedonic Attributes of Sensation. Interpretations of Sensory Scales. Units of Measurement. References.

1974, 348 pp., \$17.50/£8.25

ADVANCES IN CHILD DEVELOPMENT AND BEHAVIOR/Volume 8

edited by HAYNE W. REESE

CONTENTS: Elaboration and Learning in Childhood and Adolescence. Exploratory Behavior and Human Development. Operant Conditioning of Infant Behavior: A Review. Birth Order and Parental Experience in Monkeys and Man. Fear of the Stranger: A Critical Examination. Applications of Hull-Spence Theory to the Transfer of Discrimination Learning in Children.

1973, 312 pp., \$17.50/£8.00

ADVANCES IN EXPERIMENTAL SOCIAL PSYCHOLOGY/Volume 7

edited by LEONARD BERKOWITZ

CONTENTS: Cognitive Algebra Integration Theory Applied to Social Attribution; On Conflicts and Bargaining; Compliance, Justification and Cognitive Change; Processes in Delay of Gratification; Helping a Distressed Person: Social; Personality and Stimulus Determinants.

1974, in preparation

MULTIVARIATE ANALYSIS AND PSYCHOLOGICAL THEORY

edited by JOSEPH R. ROYCE

This volume covers such topics as: Right answers to the wrong questions; A re-examination of factor analytic personality research and its contribution to personality theory; Linear regression equations as behavior models; Multivariate approaches to the study of cognitive styles; and Causal theories of personality and how to test them.

1973, 592 pp., \$23.50/£8.20

EVOLUTION OF THE BRAIN AND INTELLIGENCE

by HARRY J. JERISON

The book presents the full scope of the organic evolution of the vertebrate brain, beginning with the earliest endocasts from late Silurian and early Devonian times, up to the evolution of the hominids and, most recently, modern man about 250,000 years ago. Dr. Jerison examines such subjects as the trend toward the increase in relative brain size and its relevancy to intelligence as an evolving behavioral capacity; the evolution of cognitive capacities for representing reality, which is treated as a necessary consequence of neural organization; and the selection pressures associated with the major evolutionary transitions.

1973, 496 pp., \$25.00/£11.75

BEHAVIOR MODIFICATION: APPLICATIONS TO EDUCATION

edited by FRED S. KELLER and
EMILIO RIBES-INESTA

This book focuses on the application of modern reinforcement theory and behavior modification techniques to the problems of education. Topics discussed include: the use of behavior modification techniques by minimally trained primary school teachers; relieving the educational deficiencies of underprivileged children by behaviorally oriented educational technology; and the attainment of effective individualized instruction at the university level.

1974, about 250 pp., in preparation

HEALTH AND ILLNESS

A Social Psychological Analysis

by CLAUDINE HERZLICH

translated by DOUGLAS GRAHAM

A Volume in the EUROPEAN MONOGRAPHS
IN SOCIAL PSYCHOLOGY Series

CONTENTS: Introduction: The Individual, the Way of Life, and the Genesis of Illness. Nature, Constraint, and Society, Mechanisms and Usage. Health and Illness. Illnesses—Dimensions and Limits. The Sick and the Healthy. The Social Representation of Health and Illness. Conceptions of Illness and Illness Behaviour. The Invalid and his Identity.

1974, 176 pp., \$10.00/£3.80

MATHEMATICAL PSYCHOLOGY

by DONALD LAMING

This book covers the areas of traditional experimental psychology in which theories are quantitative rather than qualitative. In each of these areas—human judgement, signal detection, reaction times, and learning—there are several different theoretical approaches which can be employed. This book presents the principal theories, paying particular attention to the ideas underlying each, and illustrates them with simple examples. For the most part, the text is without formal mathematical argument, except where this is deemed to assist the presentation of some important idea.

1973, 388 pp., \$23.00/£8.20

DIVERSITY

From introductory psych to factor analysis, Saunders has the texts that meet your curriculum requirements.

Leavitt:
DRUGS AND BEHAVIOR

Ideally suited for undergraduate courses in psychopharmacology, this new text covers principles of drug action, drug effects on various types of behavior, the use of chemotherapy in disorders of emotional health, and the effects of various foods on behavior. Emphasizing a behavioral approach, the author discusses: drug toxicity, profiles of drug users, therapy for drug abuse, sensation and perception, learning and memory, and creativity. By **Fred Leavitt**, California State University, Hayward. About 275 pp. Illustd. Ready late Summer. Order no. 5695.

Mikulas:
CONCEPTS IN LEARNING

Here's a vital new text devoted to the practical implications of the various issues and principles of learning. The author synthesizes the major animal findings and concepts of classical learning and relates them to current research in human learning. Education, therapy, social issues, and self-understanding are carefully examined, along with the underlying bases of the physiology of learning. By **William L. Mikulas**, University of West Florida. About 270 pp. Illustd. Ready August. Order no. 6327.

Hebb: 3rd Edition
TEXTBOOK OF PSYCHOLOGY

This outstanding introductory text is known for its consistent, logical theoretical structure. The emphasis is on behavior and theory of learning with new material on mental illness; short and long-term memory; the chemistry of memory; and the latest research evidence on perception. By **Donald O. Hebb** of McGill Univ., Montreal. 324 pp. 104 figs. \$8.50. March 1972. Order no. 4622.

DiCaprio:
PERSONALITY THEORIES:
Guides to Living

Designed for courses in adjustment as well as personality theory, this valuable new text is strongly life-oriented. The author has organized his material to cover, in turn, development, learning, needs and motivation, conflict, and the "good" or "ideal" existence. In addition, he strongly emphasizes topics that foster an understanding of individual behavior and relate directly to effective living. By **Nicholas S. DiCaprio**, John Carroll University, Cleveland, Ohio. About 500 pp. Illustd. Ready July. Order no. 3055.

Gorsuch:
FACTOR ANALYSIS

Approaching factor analysis from an applied perspective, this new book presents component and common factor analysis as variants of the general linear (matrix) model. Special attention is given to: exploratory and hypothesis testing procedures, the replication of factors, utilizing computers and when to use factor analysis from mathematical and statistical models. By **Richard L. Gorsuch**, Texas Christian University. 370 pp. Illustd. \$14.95. January 1974. Order no. 4170.

Torrey: 3rd Edition
A STUDY GUIDE FOR HEBB'S
TEXTBOOK OF PSYCHOLOGY

This pre-tested manual will help the student develop his own analyses of the concepts presented in Hebb's text. Included are multiple choice questions (with answers), commentaries illuminating Hebb's major theses, and helpful bibliographic references. By **Charles C. Torrey**, Macalester College. 142 pp. Soft Cover. \$2.95. March 1972. Order no. 8881.

Sattler:
**ASSESSMENT OF CHILDREN'S
INTELLIGENCE**

Here's a definitive new text/reference that is both a practical guide as well as a research and clinical handbook for the individual intelligence testing of children. The text covers test administration, scoring, interpretation, report writing, and consultation. Special chapters are devoted to minority group children, the diagnostic process, childhood schizophrenia, mental retardation, organic brain damage, learning disabilities, and emotional disturbance. Tests covered include the Stanford-Binet, WISC, WPPSI, PPVT, CMMS, Leiter, Quick, PTI, and Slosson. Over 1200 studies are reviewed. Instructor's Manual of test items available. By *Jerome M. Sattler, San Diego State University*. 526 pp. \$13.95. January 1974. Order no. 7943.

Rosen, Fox & Gregory: 2nd Edition
ABNORMAL PSYCHOLOGY

An unusual, intriguing text for undergraduates. Integrates psychoanalytic theory, experimental psychology and practical clinical experience with relevant research in related fields. Difficult and often controversial subjects are handled from a wide range of viewpoints. And every chapter in this second edition has been thoroughly rewritten and revised. By the late *Ephraim Rosen of the Univ. of Minn., Ronald E. Fox and Ian Gregory, both of Ohio State Univ.*, 516 pp. Illustd. \$11.50. March 1972. Order no. 7696.

Millon: New 2nd Edition
**THEORIES OF PERSONALITY &
PSYCHOPATHOLOGY**

This book offers students the opportunity to read the actual writings of major psychologists rather than just reading about them. The author groups the major theories of abnormal psychology by the kinds of data they emphasize—*biophysical, intrapsychic, phenomenological or sociocultural*, and then presents representative papers in which leading theorists of each school (such as Sheldon, Freud, Rogers, and Skinner) discuss the etiology, pathology, and therapy of abnormal behavior. Edited by *Theodore Millon, Univ. of Illinois*. About 500 pp. Illustd. About \$5.95. Ready April. Order no. 6382.

Millon & Millon:
**ABNORMAL BEHAVIOR AND
PERSONALITY**
A Biosocial Learning Approach

This informative, eclectic undergraduate text is ideally suited to the student's first course in abnormal psychology. The authors strongly emphasize the development of personality characteristics—they impart the knowledge by skillfully drawing on the student's familiarity with the psychologically relevant experiences encountered in daily life. They examine all viewpoints, and their treatment of the subject matter is unusually wide-ranging. Elucidated are all approaches to abnormal behavior—the behavioral, psychoanalytic, phenomenological, biophysical, and sociocultural. A workbook to accompany this text will soon be available. By *Theodore and Renee Millon, both of the University of Illinois*. About 500 pp. Illustd. Just Ready. Order no. 6390.

Johnson:
**AGGRESSION IN MAN
AND ANIMALS**

This valuable supplement for any undergraduate course in psychology cuts across disciplinary lines to present a broad-based treatment of all aspects of aggressive behavior in man and animals. The author discusses aggressive tendencies and behavior in more than 150 species. He also probes current social problems in depth and detail. By *Roger N. Johnson, Ramapo College of New Jersey*. 269 pp. Illustd. Soft Cover. \$3.95. April 1972. Order no. 5160.

Whittaker:
**RECENT DISCOVERIES IN
PSYCHOLOGY:**
Readings for the Introductory Course

An exciting new supplement designed to stimulate and involve the student. Every article in this relevant new reader was written within the last ten years. Covered in detail are topics such as invasion of privacy in the investigation of human behavior, perception and judgement in the political extremist, the adolescent "hippie," and psychological alternatives to war. Edited by *James O. Whittaker of Penna. State Univ.* 448 pp. Soft Cover. \$5.50. January 1972. Order no. 9325.

To order—Turn page and fill in coupon

W. B. SAUNDERS COMPANY
West Washington Square, Philadelphia, Pa. 19105

Millon: MODERN PSYCHOPATHOLOGY

This stimulating text for the first course in abnormal psychology captures the student's interest because it pays particular attention to the conditions most familiar and important to him—the milder pathological syndromes. These disturbing but not disabling disorders, which the student will recognize from his own experience, are presented in such a way that they help the student to understand the major syndromes. Psychopathology is seen as a coherent continuum, ranging from the mildest deviations from the norm to the most severe psychotic states. *By Theodore Millon, Univ. of Illinois.* 681 pp. Illustd. \$10.75. Sept. 1969. Order no. 6385.

Skinner: NEUROSCIENCE: A Laboratory Manual

A comprehensive introduction to the neuroscience laboratory for the psychology student. Shows how the neural elements of the brain work and how they operate together in systems. Describes techniques for experiments on the brain, including stereotaxic surgery, sites for histological examination, and construction of intracranial implant devices. *By James E. Skinner of the Baylor College of Medicine.* 244 pp. 211 figs. \$6.95. Soft Cover. April 1971. Order no. 8345.

Stotland & Canon: SOCIAL PSYCHOLOGY, A Cognitive Approach

Here is a new, provocative text which examines the way in which we are "programed" by experience to react and respond to various and varied life situations. Essential principles are presented and applied to areas such as interpersonal perception, communicational learning, conformity, self-esteem, and action and decision. *By Ezra Stotland and Lance Canon, both of the Univ. of Washington.* 592 pp. Illustd. \$11.95. September 1972. Order no. 8608.

Singer & Singer: PSYCHOLOGICAL DEVELOPMENT IN CHILDREN

This basic text in child psychology presents a unique synthesis of chronological and theoretical approaches within a unified viewpoint. The authors have placed their major emphasis on the processes of the child's development. They show how children acquire language, learn moral judgements, become socialized. Thus, it builds an understanding of why children develop as they do. *By Robert D. Singer and Anne Singer, both of the Univ. of Calif., Riverside.* 437 pp. Illustd. \$8.00. Oct. 1969. Order no. 8310.

Wallace: PSYCHOLOGY: A Social science

This highly contemporary text offers a real alternative to the traditional survey approach to introductory psychology. Focuses on human psychology as a Social Science and discusses such topics as: racism in America, the ecological catastrophe, alienation, violence, population growth, manipulation and power and much more. *By John Wallace of the Univ. of Calif., Irvine.* 429 pp. Illustd. \$9.50. January 1971. Order no. 9115.

Hardyck & Petrlovich: INTRODUCTION TO STATISTICS FOR THE BEHAVIORAL SCIENCES

An ideal introductory statistics text for students with little or no math background. The authors develop in clear detail the procedures of descriptive statistics upon which inferences are based. Each chapter includes a set of problems, and examination questions are provided in an accompanying Instructor's Manual. Also available is a WORKBOOK to accompany the text. *By Curtis Hardyck, Univ. of Calif., Berkeley; and Lewis Petrlovich, Univ. of Calif., Riverside.* Text: 302 pp. Illustd. \$7.50. Oct. 1969. Order no. 4520. Workbook: 118 pp. Illustd. Soft Cover. \$3.50. Oct. 1969. Order no. 4522.

A good book gets better

The third edition of
Elements of Psychology offers you:

- **WIDE COVERAGE.** More than half the book now covers the areas of social, abnormal, personality, developmental, and intelligence. Material on learning, motivation, and emotion has been streamlined and brought up to date. Coverage of developmental and behavioral genetics has been integrated throughout the text. **New topics** include Altered States of Consciousness; Visceral Learning; Race, Genetics and IQ; Genetic Counseling; Biological Clocks; Psychosurgery; Morality, Aggression, and Equity.
- **AUTHORITY.** Current work and thinking on each subject is critically and carefully presented. Where needed, expert advice has been obtained (e.g. Dan Slobin on Psycholinguistics, Marjorie Honzik on Intelligence, Charles Tart on Altered States of Consciousness, Michael Lerner on Genetics, John Kennedy on Perception.)
- **180 BOXES — MOST NEW OR REVISED.** These examine the history of psychology, including classic experiments; frontier areas of research; and topics of unusual interest, such as the morality of mercy killing, cross-cultural correlation of child rearing practices to the amount of crime in a society, the ethics of psychological research on humans, competition and culture, terminal patients learning to accept impending death, the psychological basis of humor, and the causes of witchcraft.
- **SUPPLEMENTARY PACKAGE.** Semi-programmed student guide, with 2500 fill-in questions; behavioral objectives unit workbook, utilizing the Keller method of personalized instruction; behavioral objectives instructor's guide, with four mastery tests for each unit and 300 multiple choice examination questions keyed to the behavioral objectives for each unit; Instructor's Manual with 600 multiple choice test items in card form; glossary pamphlet free to each student.

A New, Fresh Approach to Introductory Psychology

UNDERSTANDING HUMAN BEHAVIOR

by James V. McConnell of the University of Michigan

Comprehensive, dramatic introduction to principles of psychology emphasizing positive, constructive and rewarding approach to learning.

Human behavior analyzed from three points of view: *intrapsychic, biological, and social/behavior.*

Fictionalized case histories, experiments and illustrative stories provide intriguing preview of chapter content. Topics include: Sperry's split-brain work, Rosenhan's work on accurate sanity diagnosis.

Personal and social concerns fully developed in both textual and fictional material. Topics include: biofeedback, Transactional Analysis, human sexuality.

Research experiments presented from point of view of experimenter (why he/she planned it that way) and the subject (how he/she perceived the experiment).

Running glossary contains definitions of psychological terms, more difficult everyday words, related references, author's comments, and chapter summaries.

REVIEWER COMMENTS:

"I was immediately struck by the high readability of the chapters and the fictional vignettes beginning and ending each chapter. There is little doubt that J. V. McC. has apprehended his goal: an introductory psychology text written for all students."
Elliot Entin, Ohio University

"Overall, I would have to say that the work is very thorough, scholarly and well written, giving significant concepts in a generally interesting manner. It should appeal to students at a variety of intellectual levels."
Robert Hoepfner, Orange Coast College

"My general impression is that you've got a winner."
Charles G. Halcomb, Texas Tech University

720 Pages/February 1974/\$10.95 (tentative)

Also Available to Accompany the Text—
STUDENT MANUAL by Lawrence Al Siebert, Oregon State System,
and Timothy Walter, Rhode Island College

Provides a complete review of the textual material, a series of "prescriptions" on how to study and how to pass exams, detailed step-by-step reviews of chapter material, true-false test questions, individual action projects, and readings.
128 Pages/February 1974/\$2.50 (tentative)

INSTRUCTOR'S MANUAL by Lawrence Al Siebert and Timothy Walter.
Includes chapter summaries, content objectives (major learning points), list of films and sources, and suggested class demonstrations.

Important New Biofeedback Reference Books from Aldine

THOUGHT AND FEELING: Cognitive Alteration of Feeling States edited by HARVEY LONDON and RICHARD E. NISBETT

This book consists of experimental studies that derived from and extend Schachter's theory of emotional states and Heider's attribution theory. The papers deal with a wide variety of topics—for example, aggression, boredom, obesity, the control of pain, and delusional systems. Each of the authors

takes the theoretical concept of cognition and relates it to research he is currently doing. Thus the book bridges the gap between cognitive theory and the utilization of that theory in the applied research that is being done today.

164 pp. \$8.95 April 1974

CARDIOVASCULAR PSYCHOPHYSIOLOGY: Current Issues in Response Mechanisms, Biofeedback and Methodology

edited by PAUL OBRIST, A. H. BLACK, JASPER BRENER and LEO V. DICARA

This book—of original papers by leading authorities on the subject—offers the first comprehensive overview of the entire field of cardiovascular psychophysiology. Part I provides an overview of the subject and of the major contemporary measurement techniques. Part II contains experimental studies of cardiovascular function dealing with the interactive nature of cardiovascular and behavioral events. Part III is concerned with the operant conditioning of auto-

nomous responses in animals. Part IV turns to the human subject, with an analysis of operant autonomic training procedures and the therapeutic use of operant conditioning techniques. Part V focuses on heart rate and its relation to sensori-motor processes. The book ends with a summary by the four editors, and a remarkable Bibliography of nearly 1,000 items.

MEASUREMENT IN THE SOCIAL SCIENCES: Theories and Strategies

edited by H.M. BLALOCK, JR.

This book deals with selected problems of measurement and is organized so that, in general, one proceeds from problems of data collection to those of data analysis. It represents a series of studies of topics that are deemed to be crucial for the advancement of social science research but which have not received sufficient attention. The purpose

is to stimulate further methodological research on measurement and to study the ways in which knowledge that has been accumulated in some fields may be generalized so that it may be applied to others.

SCALING: A Sourcebook for Behavioral Scientists

edited by GARY M. MARANELL

This book provides a broad and detailed description of the major processes for developing measurement scales. The articles—both classics in the field and the best of modern work—require no great mathematical sophistication, and go well beyond the conventional study of attitudes to the more general uses of scaling. They enable the student and researcher to examine the development of measures of scalability and the problems and weaknesses they present, to

become familiar with the development of tests of significance for reproducibility and scalability and the need for them, and to examine the lively history of the subject and experience the excitement that can be secured from sharing with a creative author the first report of his insight.

416 pp. \$15.00 cloth

RESPONSE EFFECTS IN SURVEYS: A Review and Synthesis

by SEYMOUR SUDMAN and NORMAN M. BRADBURN

This book is the first major effort to pull together the voluminous literature on the subject of response effects into a single source, and to develop a model of the major kinds of response error and a general theory of response effect. The authors present a general framework for studying this problem, and use that framework to examine literally hundreds of methodological studies, in order to

determine what is known about the causes and magnitudes of various types of responses. Users and practitioners of survey methods in all fields will find the book useful as a summary statement of important principles of sound research methods and a guide to the improvement of survey work.

Biofeedback - Medicine, Therapy, and Research:

- ☐ Stress Related Disorders
- ☐ Physical Therapy and Rehabilitation
- ☐ Brain-Wave Training
- ☐ Right Brain, Left Brain Training
- ☐ Psychosomatic Dysfunction

Conscious control over the **autonomic** systems of the body is the promise which biofeedback training offers to medicine, therapy, and research. The potential applications of this new methodology have opened some of the most interesting avenues in psychological investigation.

One of the most widely used applications is the feedback of myo-electric activity for the release of muscular tension in the head, neck, and back. With the guidance of a professional, the subject or patient learns to use the feedback signal as an indication of muscle relaxation. The state of **deep** muscle relaxation is a necessary condition for many varieties of therapy and training.

Teaching children to *think* is universally regarded as the most important function of education. But how can this ideal be translated into effective classroom activities, especially at the primary and pre-primary level? In response to this challenge, Hans G. Furth, noted psychologist and student of Jean Piaget, and Harry Wachs, a practicing optometrist with experience in special education, have developed a unique curriculum, using Piaget's seminal theories as their base. Their design permits freedom with the structure of the learning games described in detail in their new book. Tested in actual teaching situations, using only the simplest equipment, suitable for home as well as school use, and designed to offer maximum flexibility, these games provide a unique and practical way to make thinking part of every young child's education.

THE MIDDLEBROOK EFFORT

It's only four months old, but Patricia Niles Middlebrook's
SOCIAL PSYCHOLOGY AND MODERN LIFE
is fast becoming the leading text in its field. Here's why:

"Middlebrook relates everyday experience with hard core lab studies of social psychological phenomena. It's hard to find these two together without the loss of some information. But **Middlebrook accomplishes this flow that most books do not.**"—Carl Greenberg, *Wayne State University*

"It's very good."—H. C. Triandis, *University of Illinois*

"I am very impressed with Middlebrook's ability to integrate the very latest research findings in so many areas. The chapter on altruism is quite well done and an important addition."—Ronald L. Cohen, *Bennington College, Vermont*

"An authoritative and well written presentation of social psychology for undergraduates. The book should become a **classic in its field.**"—John R. Silvestro, *State University College at Fredonia, New York*

"**Most dynamic text I have reviewed:** uses every technique and feature to encourage and motivate students to read not only text but do further research."—Cecil P. Jones, *Daytona Beach Community College, Florida*

"A **creative, lively, and integrative** book with **high readability** and **coverage of relevant topics.** Students will find it intriguing and thought provoking."—Raymond F. Paloutzian, *University of Idaho*

"I had already chosen another text before I received the book you sent. I was **sufficiently impressed** with it to **revise my order.** The section on altruism particularly is as comprehensive and up to date as one could hope for."—Ira Silverman, *University of Rhode Island*

SELECTED PAPERS OF DAVID WECHSLER

by DAVID WECHSLER

with introductory material by
ALLEN J. EDWARDS

Here is a comprehensive, wide ranging compendium of the work of one of the twentieth century's foremost psychologists—David Wechsler. Perhaps best known as the author of the WAIS, WISC, and WPPSI, Wechsler has made important contributions to many areas of theoretical and clinical psychology. This book reflects that breadth, ranging as it does from his earliest work in experimental psychology to his later concerns with the very nature of intelligence and its role in the modern world.

Among the original concepts and important problems discussed in the book are:

- Non-intellective factors in intelligence
- Global intelligence
- The use of deviation IQ at all age levels
- The difference between machine and human intelligence
- The range of human capacities
- The role of intelligence in the modern world

This book will be both fascinating and valuable to all clinical, school, and counselling psychologists, personality psychologists, and users of the Wechsler Scales of Intelligence.

1974, in preparation

The first thing
we did with our
Human Development
series...

Was to find
a good-looking hero.

You see, our film strip series deals with real people—not cartoon characters. And through these real people you are offered a challenging look at the first 2½ years of life — the crucial years.

Effects of day care centers . . . sequence of language acquisition . . . effects of sensory stimulation on intellectual and emotional development. Human Development offers a provocative Old-vs-New cross-section of the theories and findings of the most noted authorities, including Piaget, White, Kagan and Bower.

Designed for students of education, psychology, home economics, and the social sciences, Human Development is far less expensive than movies — and far too important to overlook.

FOR THE HUMANISTIC APPROACH

From Holt, Rinehart & Winston-

READINGS IN PERSONALITY

Edited by Harriet N. Mischel and Walter Mischel, *both of Stanford University*

This collection of articles presents major theories, issues, and research in personality. While the selections parallel the organization of Mischel: *INTRODUCTION TO PERSONALITY*, this book has been designed to serve as a complete independent volume. Extensive introductory material is provided to aid the reader in understanding the concepts presented by the individual articles. Selections in Part I offer samples of some of the major theoretical orientations to personality and their associated assessment techniques and applications. Part II covers personality development and basic processes.

1973/494 pages/\$6.95 paper

INTRODUCTION TO PERSONALITY

Walter Mischel, *Stanford University*

"Viewed strictly as a teachable undergraduate text, Mischel's new volume seems better organized, more clearly presented, and the most effective new work. While it carries a social learning, behaviorist orientation, it presents the major issues in the field in a succinct and remarkably pointed fashion so that the more humanistically oriented instructor can use the book to good advantage." Jerome L. Singer, *Yale University*, from the 1972 *ANNUAL REVIEW OF PSYCHOLOGY*.

Instructor's/Test Manual

1971/544 pages/\$11.00

MAINSTREAM PSYCHOLOGY: A Critique

Benjamin M. Braginsky, *Wesleyan University*, and Dorothea D. Braginsky, *Fairfield University*

MAINSTREAM PSYCHOLOGY reviews and analyzes the role of psychology as a profession and as a social force. Avoiding technical jargon, the book includes an analysis and critique of the methodology, theories and practices of psychology with particular focus on behaviorism and humanism. The book provides a social psychological model for understanding and evolution and development of the field, and integrates disparate criticisms of psychology and other social sciences into one comprehensive framework.

March 1974/192 pages/\$4.50 paper; \$7.95 hard cover (tent.)

BEHAVIORAL SELF-CONTROL

Carl Thoresen, *Stanford University, School of Education*, and

Michael J. Mahoney, *Pennsylvania State University*

As man becomes more concerned about the advances of systematized behavior control, the importance of personal freedom and humanistic choice become more apparent. *BEHAVIORAL SELF-CONTROL* points out that the technology of behavior change can be meaningfully and productively self-applied toward personalized goals. Blending humanistic concerns and behavioral means, this interdisciplinary book offers a comprehensive data-oriented review and evaluation of existing theory and research on self-control.

January 1974/192 pages/\$3.65 paper (tent.)

THE PERSON IN PSYCHOLOGY SERIES Edited by Theodore R. Sarbin, *University of California, Santa Cruz* NEW

HOW TO DO PSYCHOTHERAPY AND HOW TO EVALUATE IT: A Manual for Beginners

John M. Gottman, *Indiana University*, and Sandra R. Leiblum, *Rutgers Medical School*

Integrating behavioral, cognitive, and systems psychotherapies, this book 1) provides a step-by-step overview of the process of psychotherapy; 2) integrates behavioral and dynamic approaches; 3) avoids jargon in telling the therapist what he can do and in what situation; 4) suggests ways of evaluating therapy; and 5) is a directory of other useful sources.

January 1974/192 pages/\$3.50 paper (tent.)

CAN YOU BELIEVE WHAT THEY'RE SAYING ABOUT KENDLER

They're saying that Howard Kendler's Third Edition of **BASIC PSYCHOLOGY** is even better than the Second Edition.

They say it emphasizes the scientific method in the context of significant human behavior, integrating three main themes: (1) The study of psychology must be based on evidence, (2) All major principles and psychological theories should be fairly represented, and (3) Psychology

can also be studied in relation to meaningful social issues.

We say, decide for yourself.

Write today for a complimentary copy of **BASIC PSYCHOLOGY**, Third Edition. Upon request, we'll also enclose the supplements: **STUDY GUIDE** for **BASIC PSYCHOLOGY** by Tracy Kendler and the **UNIT WORKBOOK** for P.S.I. by Jeffrey Corey and James McMichael.

RACE

by John R. Baker

Written with a thoroughness uncharacteristic in the usual treatment of this subject, *Race* is the only book which embraces history, biology, paleontology, the ancestry of man, his ascent to civilization, and the psychology of race.

"No book known to me tries to encompass everything relevant to the idea of race with such thoroughness, seriousness and honesty."

—Sir Peter Medawar

"With Professor Baker's book we have at last a compendium of biological facts about the various groups of men—a compendium which can provide a factual basis for discussions of racial differences."—René Dubos

"A most impressive display of profound scholarship and vast erudition... essential."

—Arthur R. Jensen

"A tough-minded scholar and scientist (biology) attacks the subject with a fresh vocabulary and clearly defined terms and assails a lot of old clichés."—*Publishers Weekly*

A New Book! HUMAN DEVELOPMENT: The Span of Life. This new text uniquely covers the entire life cycle—from conception through old age and death. It encompasses emotional, moral and social factors, as well as physical growth and development, in a descriptive rather than experimental approach. A glossary of terms is included. By **GEORGE KALUGER, Ph.D.**; and **MERIEM FAIR KALUGER.** April, 1974. Approx. 336 pages, 44 illustrations. About \$9.95.

A New Book! HUMAN EXPERIENCE: A Psychology of Growth. Covering all aspects of the life cycle, this new text deals with fundamental psychological concepts as well as unique considerations such as adjustments to dramatic changes in lifetime styles; relationships and conflict; etc. By **RONALD G. POLAND, Ph.D.** February, 1974. 288 pages plus FM I-XII, 7" x 10", 31 illustrations with graphic abstractions by **KAREN SWEIKHARDT.** Price, \$7.95.

A New Book! ISSUES IN PHYSIOLOGICAL PSYCHOLOGY. Centered on current and often controversial issues, this excellent book of readings reflects the recent research and thinking of distinguished scientists. Articles explore the physiology of dreaming, memory storage processes, evolution of sleep, etc. Edited by **FRANCIS LEUKEL.** January, 1974. 340 pages plus FM I-VIII, 7" x 10", 132 illustrations. Price, \$6.95.

A New Book! INTERVENTION IN HUMAN SERVICES. The first human service training text to focus on skills development, this new book blends the experimental and didactic to build basic skills of observation, recording, and reporting, then more complex skills of interviewing and counseling. Case studies are provided. By **EVELINE D. SCHULMAN.** May, 1974. Approx. 264 pages, 7" x 10", 24 illustrations. About \$7.50.

Explore the mind of today's man— with Wiley-Interscience books

1. SIMULATION IN HUMAN SYSTEMS:

Decision-Making in Psychotherapy

By Richard Bellman and Charlene Paule Smith, both of the *University of Southern California*

A volume in the Wiley-Interscience series in Operations Research, edited by David B. Hertz

Illustrates certain contemporary mathematical concepts and methods applied to decision processes occurring in a human interaction system; introduces the powerful and versatile technique of simulation; and describes how computers may be used to increase the effectiveness of simulation processes used in research and teaching.

0 471 06414-9 1973 205 pages \$13.95

2. AFTER SUICIDE

By Samuel E. Wallace, *New York University*

Foreword by Theodore Caplow

How did twelve women survive their husbands' suicides? Exploring the experience of women confronted with this loss, Samuel E. Wallace shows how people confront, experience, and live through life-threatening crises.

0 471 91865-2 1973 269 pages \$9.95

3. NEW APPROACHES TO PSYCHOLOGICAL MEASUREMENT

Edited by Paul Kline, *University of Exeter*

Describes all the major areas of theory, technique, and application in psychological measurement.

0 471 49120-9 1974 264 pages \$15.95

4. EVALUATING TREATMENT ENVIRONMENTS:

A Social Ecological Approach

By Rudolf H. Moos, *Stanford University*

A volume in the Wiley-Interscience series in Health, Medicine, and Society, edited by David Mechanic

Offers new, unique methods for evaluating the social milieus of both hospital and community treatment programs.

0 471 61503-X 1974 388 pages \$15.95

5. PERSONAL RELATIONSHIPS AND PERSONAL

CONSTRUCTS: A Study of Friendship Formation

By Steven W. Duck, *University of Lancaster, England*

What are the causes of attraction, of friendship, of love or of marital choices? Why do we get on better with some people than we do with others? This book answers these and other questions of everyday importance, and discusses the specific problem of how friendships develop.

0 471 22356-5 1974 192 pages \$12.00

6. THINKING: ITS NATURE AND DEVELOPMENT

By John Radford and Andrew Burton, both of *North East London Polytechnic*

A general text on thinking. Discusses creative thinking, language and thought, imagery, models, and more.

0 471 70476-8 1974 432 (approx.) \$16.50 (tent.)

7. FORMATIVE YEARS IN BUSINESS:

A Long-Term AT&T Study of Managerial Lives

By Douglas W. Bray, Richard J. Campbell, and Donald L. Grant, all of the *American Telephone and Telegraph Company*

Presents information on the growth and development of 274 managers during their first eight years of employment in the Bell System. The book is thorough, covering recruitment of the young managers, what they were like upon employment, and changes in their ability, motivation, and personal lives.

0 471 09810-8 1974 236 pages \$12.95

8. THE CHANGING SCHOOL SCENE: CHALLENGE TO PSYCHOLOGY

By Leah Gold Fein, *American Board of Professional Psychology*

Foreword by Samuel M. Brownell

A volume in the Wiley series on Personality Processes, edited by Irving G. Weiner

Explores the innovative, experimental, and compensatory programs in the public schools. Gives special attention to the changes and problems of schools in deprived areas.

0 471 25694-3 1974 336 pages (approx.) In Press

9. THE EFFECT OF THE INFANT ON ITS CAREGIVER, Volume 1

By Michael Lewis, *University of Pennsylvania*, and Leonard A. Rosenblum, *State University of New York*

A volume in the Wiley-Interscience series *The Origins of Behavior*, edited by Michael Lewis and Leonard A. Rosenblum

Examines the effect that the infant may have on its caregiver. Focuses particularly on the infant as a source of the formation, regulation, and even the malevolent distortion of the caregiver's behavior.

0 471 53202-9 1974 288 pages (approx.) \$14.95 (tent.)

10. THE LOGIC OF THE LIVING BRAIN: An Enquiry into the Neural Correlates of the Higher Brain Functions

By G. Sommerhoff, *University College, London*

Analyzes the higher brain functions as phenomena *sui generis*, thus breaking away from facile comparisons with servomechanisms, computers, and 'intelligent machines.' At the same time it shows how the phenomena may be conceived in neural terms.

Iconic Communication

An Annotated Bibliography

W. H. HUGGINS and
DORIS R. ENTWISLE

Iconics is the study of communication via visual forms whose meaning is conveyed in the forms themselves rather than by some arbitrary convention. Focusing on how visual images may communicate information to human beings, the study pulls together concepts from perception, psychology, social anthropology, education, and computer graphics. The authors assert that portrayal of concepts via moving images and symbols of a radically new genre could mean a revolution in education, psychology, and other areas. The authors also assert that graphic images will increasingly be used to create visual information not previously perceivable in the natural environment. \$8.50

MENTAL HEALTH ISSUES AND THE URBAN POOR

Edited by Dorothy A. Evans and William Claiborn
Pergamon General Psychology Series, Volume 44

Provides an in-depth analysis of the problems that the mental health fields are having in serving the urban poor. The crucial issues in the status and future of mental health service to the poor are presented in a series of papers by the major figures in community mental health. Important workers such as Reiff, Lerner, Riessman and Billingsley discuss the major theoretical and practical issues in the delivery of service, the training of service, and the evaluation of service to the urban poor. The result is a major sourcebook for training mental health workers.

CONTENTS

Introduction. Social Action and Community Mental Health. The Social Responsibility of Community Mental Health Centers; Robert Reiff. Victim Blame and Mental Health. The Struggle for Mental Health; Andrew Billingsley. Consumer Sensitive Program Planning and Evaluation. Service Effectiveness and the Problem of Evaluation; Frank Riessman. Social Values and Mental Health Practices. Is Psychotherapy Relevant to the Needs of the Urban Poor? Barbara Lerner. Mental Health and Social Systems. Community Mental Health From a "Change Agent" Point of View; Lawrence Schlesinger. Federalism and Funding of Mental Health Programs. National Trends

in the Financing of Mental Health Programs; Henry A. Foley. Toward an Equitable Therapy for the Poor. A Missing Component in Mental Health Services to the Urban Poor; Services In-Kind to Others; Carl Goldberg and Joyce D. Kane. Community Based Training. Training Residents in Outer Space; Jules M. Ranz and Peter B. Dunn. A Model of Service to Youth. Making Innovative Community Mental Health Programs Marketable; Milton F. Shore. Advocacy and Activism. The Role of Advocacy in Community Mental Health: Two Case Presentations; Zelda A. Wolpe. Summary and Conclusions.

CREATING CHANGE IN MENTAL HEALTH ORGANIZATIONS

By G.W. Fairweather, D.H. Sanders, L.G. Tornatzky and R.N. Harris, Jr.
Pergamon General Psychology Series, Volume 42

Presents a national experiment that systematically evaluates the social change process. 250 mental hospitals participated in an experiment whose purpose was to establish an innovative mental health program in each community as an alternative to the mental hospital. The result was a new community model, called *the lodge society*, which evolved from the five year experiment.

The experiment: 1) Explored how mental hospitals can be persuaded to adopt the new model. 2) Discovered the most effective techniques to implement the lodge society once the program is adopted. 3) Explored how the lodge society may be extended to other mental health programs. The results are summarized as a list of principles for social change.

CONTENTS

The Need for Social Change in Treating Mental Illness. The National Experiment: Organizational Change, Background and Research Plan. The Process of Approach and Persuasion. Factors Affecting the Decision to Adopt. The Process of Activating Adoption. The

Essential Conditions for Activating Adoption. Follow-Up Diffusion of the Community Lodge. Principles for Creating Change in Mental Health Organizations. Social Policy Decisions Aimed at Solving Human Problems.

Love, Sex & Marriage

THROUGH THE AGES

BERNARD I. MURSTEIN

Foreword by William S. Kephart

Marriage, its functional evolution, and its contemporary variations are brought into vivid perspective in this historical cross-cultural study. The rise of feminism and an assessment of the current viability of marriage are among other highlights, which include the latest information on today's innovations from theoretical, literary, and empirical research bases.

Chapters include: Marriage in the Old Testament; among the Greeks; Roman marriage; early Christian views; the Middle Ages; courtly love; Renaissance and Reformation; the age of reason and licentiousness; Romantics and Victorians; Ellis and Freud; American marriage; the dawn of women's liberation; the sex explosion; marriage in the Soviet Union; in Africa; Japan; overview; and more.

April, approx. 620 pages, \$16.00 tent.

The *American Psychologist* is the official publication of the American Psychological Association and, as such, contains archival documents as well as material submitted by authors. Articles should be timely and of broad general interest to psychologists of all scientific and professional persuasions. Manuscripts must adhere to the instructions on reference citations, preparation of tables and figures, manuscript format, etc., as described in the *Publication Manual of the American Psychological Association*. Manuscripts that do not conform to the style set forth in the *Manual* will be returned for revision. When in doubt about practices of the Journal, authors should examine a recent issue.

Articles under consideration or accepted by another periodical of general circulation are not acceptable. Also, articles accepted for publication by this Journal may not be reprinted elsewhere without APA permission. Comments should be submitted no later than two months from the date of the issue containing an article on which comment is made in order to ensure timeliness. Submit manuscripts in triplicate, accompanied by a 100-120-word abstract, to Kenneth B. Little, American Psychological Association, 1200 Seventeenth Street, N.W., Washington, D.C. 20036.

Statements contained in the *American Psychologist* are the personal views of the author and do not constitute APA policy unless so indicated. APA reserves the right to edit all copy and to refuse ads that are not in consonance with the principles of Title VII of the Civil Rights Act of 1964 (Equal Employment Opportunity).

Written permission must be obtained from the APA for copying or reprinting text of more than 500 words, tables, or figures. Address requests to the Permissions Office.

The American Psychological Association, founded in 1892 and incorporated in 1925, is the major psychological organization in the United States. The purpose of the APA is to advance psychology as a science, and as a means of promoting human welfare. It attempts to accomplish these objectives by holding annual meetings, publishing psychological journals, and working toward improved standards for psychological training and service.

In addition to the *American Psychologist*, the Association publishes 13 other journals: *Contemporary Psychology*, *Developmental Psychology*, *Journal of Abnormal Psychology*, *Journal of Applied Psychology*, *Journal of Comparative and Physiological Psychology*, *Journal of Consulting and Clinical Psychology*, *Journal of Counseling Psychology*, *Journal of Educational Psychology*, *Journal of Experimental Psychology*, *Journal of Personality and Social Psychology*, *Professional Psychology*, *Psychological Bulletin*, and *Psychological Review*. The APA also publishes *Psychological Abstracts*, the *APA Monitor*, a monthly *Employment Bulletin*, the *Biographical Directory*, the *Convention Program*, and the *Catalog of Selected Documents in Psychology*.

Open a New Window

Validities and Values in Psychological Measurement

ROBERT M. GUION *Bowling Green State University*¹

In the musical, Mame tells young Patrick that excitement and a full life come not from unimaginative adherence to routine but from change and new perspectives. She advises him to "open a new window," to "travel a new highway that's never been tried before" She is too shrewd to leave it entirely to him; she herself opens the windows and doors to introduce new challenges.

Maybe it is too fanciful to place Congress in the role of the uninhibited Mame, or the field of industrial and organizational psychology in the role of the naïve Patrick; nevertheless, Congress did open a new door for us when it passed the Civil Rights Act of 1964. It was opened wider by the Office of Federal Contract Compliance and the Equal Employment Opportunity Commission when they issued regulations for the validation of tests and other selection procedures. Their documents directed readers to the *Standards for Educational and Psychological Tests and Manuals* (APA, 1966), but readers found the *Standards* wanting in clarity. So, in the form of a joint committee, the American Psychological Association, the American Educational Research Association, and the National Council on Measurement in Education walked through that door to survey a highway that, even if "tried before," seemed strangely obscure.

Presidential addresses come in two forms. Some are research reports; those of us without long-term research programs offer exhortations. This is the latter type. My exhortation is a plea to psychologists to look over new vistas, but to do so with less than Mame's impulsive enthusiasm. I advo-

cate thorough and careful exploration of new terrain lest we, like Mame's Beaugregard, "fall off a damned Alp." My comments are based on my work during the last two years as a member of the joint committee. I speak only for myself, not for the committee. I want to share with you my personal conclusions about the meaning and implications of what we have said about validity. My comments necessarily are elementary because elementary concepts seem so often ignored.

Definitions of Validity

Validity, in the history of testing, has been a confused concept, although the basic ideas have been present from the beginning. Criterion-related, content, and construct validities were all implicit when Galton said,

One of the most important objects of measurement . . . is to obtain a general knowledge of the capacities of man by sinking shafts, as it were, at a few critical points. In order to ascertain the best points for the purpose, the sets of measurements should be compared with an independent estimate of the man's powers. We may thus learn which of the measures are most instructive [DuBois, 1970, p. 22].

The criterion problem was acknowledged by Hull (1928): "the most formidable problem encountered by the aptitude psychologist is the location of a trial group of subjects from whom a *valid* and reliable quantitative criterion of *aptitude* may be obtained [p. 374, italics added]."

The construct problem was in Brigham's (1930) complaint:

Most psychologists working in the test field have been guilty of a *naming fallacy* which easily enables them to slide mysteriously from the score in the test to the hypothetical faculty suggested by the name given to the test. Thus, they speak of . . . perception, memory, intelligence, and the like while the reference is to a certain objective test situation [pp. 159-160].

Brigham was particularly critical of combining independent tests and giving the composite a unitary name. If tests are independent, he argued, they

¹Presented under the title "Open A New Window" as the presidential address to the Division of Industrial and Organizational Psychology at the meeting of the American Psychological Association, Montreal, Canada, August 29, 1973.

Requests for reprints should be sent to Robert M. Guion, Department of Psychology, Bowling Green State University, Bowling Green, Ohio 43403.

are measuring different things and therefore should not be given a common name. If he were addressing you, his title might come from a different song: "When will they ever learn?"

Constructs, content sampling, and relations with criteria were all intertwined in discussions of validity as the extent to which tests measure what they "purport" to measure (Boynton, 1933; Hunt, 1937; South, 1938). The 1954 *Technical Recommendations* clarified things somewhat, but the "clarification" sparked controversy, such as the opposing positions of Bechtoldt (1959) and Loevinger (1957). Content validity was largely ignored outside of educational circles; industrial psychologists certainly paid little attention to it until the term was thrust upon them in federal regulations. Nearly 20 years after the "clarification," debate still rages over the meanings of these terms. What's more, because of legal issues we have a different term, *job-relatedness*, which must somehow fit into the scheme.

I offer here my understanding of what these terms mean, and I shall illustrate that understanding with examples from a study of packers.²

Workers on this job packed their products—golf balls—a dozen to a carton. Two types of assessment were considered as possible predictors. There was a series of anthropometric measures, of which I shall concentrate only on the simplest, arm length. The other was a home grown dexterity test. The criterion was a brief work sample: the time required to pack a set of eight cartons.

CRITERION-RELATED VALIDITY

Criterion-related validity is the extent to which scores on one variable, usually a predictor, may be used to infer performance on a different and operationally independent variable called a criterion. For convenience we often speak of criterion-related validities in terms of correlation coefficients, but the statistic has nothing to do with the definition.

We can describe two of the measures in the packing study in conventional criterion-related terms. Arm length correlates with speed in packing with a coefficient of $-.46$; the validity coefficient for the dexterity test is $-.41$. These seem quite satisfactory.

The names of the predictors are not important. The information about validity is in the correlation coefficients and the regression equations on which they are based. The information I have given would have been as complete had I simply said that variables A and B have validities of $-.46$ and $-.41$, respectively. The nature of the measurement is not what is important to this statement. The important fact being reported is that these variables can be used to predict job performance within the limits of accuracy defined by the correlation coefficient.

The criterion in this conventional validation study is quite different from the sort of criterion desired by early testers. In contemporary practice, a criterion usually grows out of a given problem. The problem here is straightforward: How can we select people who will package golf balls more quickly? Pioneers in mental measurement phrased a different question: How can we find a measure in real life that will reflect the attribute our test is measuring? They would have accepted job performance as a criterion for dexterity, but looking for a criterion for a measure of arm length would have seemed awfully silly to them.

The point is that criterion-related validities serve two distinctly different purposes. In some cases, as in the early history of testing, the emphasis is on the test. In other cases, as in selection research, the focus is on the criterion. In the first type, one refers to the validity of the test scores. In the latter case, however, the reference is to the validity of the relationship. In the packing study the validity coefficient tells us nothing at all about one measurement other than that it tends to be related to another measurement. It gives as much information about the validity of the criterion as of the validity of the test. This is an uncommon way to look at these correlations, but it is useful; it may point to some understanding of the performance measure. Understanding criteria is every bit as important as understanding tests.

CONSTRUCT VALIDITY

When we speak of understanding, we are talking about construct validity, the degree to which scores may be used to infer how well a stated hypothetical construct describes individual differences among the people tested. Construct validity is not expressible in such simple terms as validity coefficients; it is a judgment based on many kinds of information: procedures followed in developing the test, results

² David P. Jones of Bowling Green State University and I plan to report the study elsewhere; here I refer only to those parts of the study that illustrate certain ideas.

of experiments testing specific implications of the construct, and patterns of correlations with other measures. The data used to judge the construct validity of a measure may also help to validate the construct; as data accumulate, ideas about the construct may be modified. Describing a construct is more than merely naming it.

Can any of the measures in the packing study be evaluated in terms of construct validity? What construct is being measured by the criterion? If I suggest that the construct we wanted to measure is productivity, as different from production, then I must define what productivity implies. Productivity may imply, for example, endurance at a high rate of performance over an extended period of time in varying conditions of work. Does the timing of a job sample for a few minutes imply endurance? I think not. We cannot defend the criterion in terms of construct validity unless we define the construct simply as short-term speed in packing golf balls—and in such a tautology we are more interested in reliability.

Can we praise the construct validity of the dexterity test? It so happens that we can. The construct of manual dexterity has been established in experimental and factor-analytic literature. This test has been found in factor analysis to have a substantial dexterity loading (Bourassa & Guion, 1959). This is not enough evidence, but it is some; it places this particular test in a well-established network of relationships.

What about the construct validity of the cloth tape measure used to indicate arm length? Here again is a tautology. What sort of a construct, other than physical distance from one end of an arm to the other, could we possibly have in mind? Of course we could say distance is a construct, simply declare the measurement valid, and forget the whole thing. Actually, construct validity is not a very useful idea for physical measurement. There are well-established, well-defined units by which length is measured. A tape measure is not evaluated by experimental or correlational studies placing their results in some nomological net. It is evaluated in terms of its reliability and of the accuracy of its units. These are quite different questions (Guion, 1965).

Let us examine the same three measures from the point of view of content validity. Content validity refers to the fidelity with which a measure samples a domain of tasks or ideas; it is the degree to which scores on the sample may be used to infer performance on the whole.

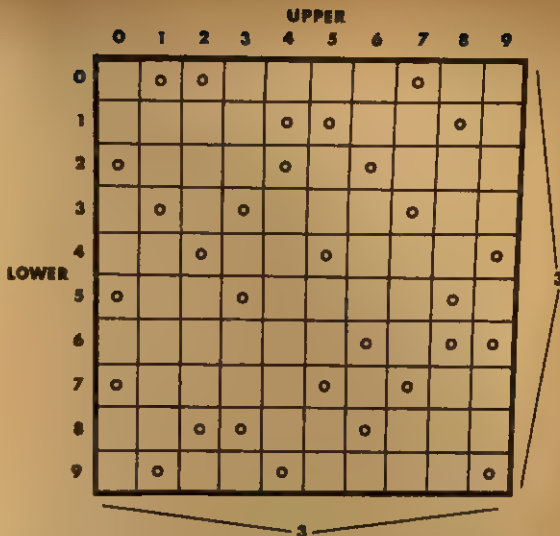

Figure 1. Sampling of arithmetic problems with equally weighted domain.

Consider a test of addition of two single-digit integers. Figure 1 defines the content domain; there are 10 possible digits for the top number and 10 for the lower. The resulting matrix allows 100 possible combinations. If the content domain is defined with every combination weighted equally, then an arithmetic test of less than 100 problems will be a valid sample of the domain if equal numbers of cells are selected for each row and each column of the matrix. With three cells in each column and each row, randomly chosen within this constraint, Figure 1 specifies a 30-item test that will be judged adequate in terms of content validity.

Figure 2. Sampling of arithmetic problems with larger integers more heavily weighted.

It is up to those concerned about content validity to define a domain appropriately for their situation. If someone defines a domain using the same matrix, but differing in the weights to be given, the 30-item test indicated here would have inadequate content validity. Figure 2 shows the changed definition: Problems using the smaller numbers have only half the weight of those using the larger ones. Relatively more items must be selected from the lower right quadrant to yield adequate content validity according to this definition of the domain.

In real industrial problems, content domains are harder to diagram, but the principles are the same. To speak of content validity, there must be a content domain from which to draw a sample. It must be analyzed in terms of elements; elements must be weighted in some way (perhaps in terms of such characteristics as frequency of occurrence, importance, or complexity); and content validity must be judged in terms of how well the domain as defined has been sampled.

The content validity of our packing criterion depends on the definition of the domain of packing tasks. If I define the domain as packing fragile items, this measure lacks content validity, for golf balls are not fragile. If the job of packing golf balls includes crating the cartons, sealing the crates, and stacking them on pallets, and if I define the content domain as including all of these activities, then this work sample lacks content validity. If, however, I define the content domain simply as the repetitive packing of cartons of golf balls as quickly as possible, then this work sample has substantial content validity.

Can we talk about the content validity of the measure of arm length? Some people will. I will not. Merely recording the number of inches encompassed in the outstretched arm does not, as far as I can tell, sample any defined domain of content. The measure is therefore not reasonably described in terms of content validity.

What about the content validity of the dexterity test? The *construct* of dexterity has been operationally defined with several kinds of related tasks; these tasks could define a content domain. The present test calls on only one of these tasks, so it is not a very good sample. Yet if I am satisfied that I am measuring the construct adequately, I am not likely to worry about content validity. Personally, I tend to think of content validity as a special case of construct validity. Where the task chosen adequately measures the construct, the need

for representative sampling of tasks is not apparent to me.

Let us take stock. What has or can be said about validity? First, for any measure there are many validities, not just one. It is and has long been recognized as silly to speak of *the* validity of a test. Second, it is an erroneous shorthand to speak of the validities of the measures themselves; what we really refer to are the validities of *inferences* from the measures (Cronbach, 1971). When we speak of *criterion-related* validity we refer to the use of test scores to infer criterion levels. When we speak of *construct* validity, we refer to the use of test scores to infer degrees to which a particular construct describes the persons, organizations, or objects measured. When we speak of *content* validity, we refer to the use of test scores to infer levels of achievement the persons, organizations, or objects would exhibit in the total domain. These are different facets or "aspects" of validity, and all three kinds of inferences should be valid for most tests. However, the kind of validity statement we seek in any given measurement situation depends on the kinds of inferences we wish to make. This is fundamentally a value judgment. Third, in industrial psychology, the most frequently valued inference is the inference about future performance on a valued criterion. The valued criterion is usually (although not necessarily) either a sample of a performance domain or a performance construct that is identifiably different from the constructs measured by predictors. That is, in employment testing, the validity of major interest is the validity of the *hypothesis* of a predictive relationship between test scores and job performance. Fourth, the validities of criteria need to be investigated. Finally, I suggest that an employment test may provide a basis for inferences that have criterion-related validity, or construct validity, or content validity, or all of these, and still not be job related.

JOB-RELATEDNESS

I am not willing to equate "validity" and "job-relatedness." Criterion-related validity is evidence of job-relatedness only if the criterion measure is a valid measure of overall job performance, an element or sample of performance, or a construct related to job behavior.

Construct validity is evidence of job-relatedness only if the construct is related to the job. To de-

fend an employment test on the basis of construct validity, one must first argue from job or need analysis that a particular construct is related to job behavior. Then he must show that the test has acceptable validity for measuring that construct. What he has at this point is the hypothesis that the construct, as operationally defined by the predictor, can be used to infer levels of valued job behavior. This is a hypothesis of criterion-related validity, and it fairly begs to be tested, "where technically feasible."

If it is clearly feasible to do the criterion-related study, it should be done. Where it is clearly *not* feasible to do the study, the defense of the predictor can rest on a combination of its construct validity and the rational justification for the inclusion of the construct in the predictive hypothesis. Where the issue is not clear, we will argue. My position is that I would rather trust the use of valid measures of predictor constructs in a well-developed hypothesis than a typical, done-for-convenience criterion-related study. I think my preference offers better evidence of job-relatedness. There are some highways, Patrick, that are better not traveled; they include those with small *ns*, low variances, or questionable criteria.

So far, these comments implied an assumption that inexperienced people will be hired who will have to learn the job. The employment test is therefore a *predictor* of performance, not a *measure* of it.³

No such assumption is made when content validity is invoked. Either experienced workers will be hired, or applicants will be expected to have already mastered certain prerequisite components of the job through prior training.

The job-relatedness of content sampling depends on the definition of the content domain. In the most extreme case, one might define job content by listing every nontrivial task performed. A representative sample from this complete catalog of

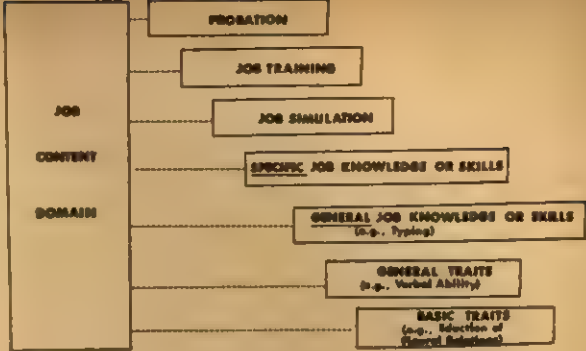

Figure 3. A progression of methods for sampling job-relevant content for the assessment of candidates.

tasks clearly has both content validity and job-relatedness. Despite its virtue, however, it can only be used to select people who already know how to handle the job. If the domain is defined more narrowly as a skill or area of knowledge that can reasonably be expected in applicants and is prerequisite to learning necessary additional skills or information, and if a test is a valid sample of this content, then the test is job related to whatever extent the domain it samples is job related.

How much abstraction is permissible before one questions whether a test is sampling *job* content? Figure 3 may clarify this problem. The large block on the left represents the defined content domain. The smaller blocks represent different ways to sample from that domain. The most direct sample, and therefore the closest, is a probationary period; what could have higher content validity than a well-planned probationary period? Next is the completion of a training program designed to teach a representative sample of job tasks. The third, a simulation exercise, can be a good sample of job content.

As we move to the right, to the use of conventional tests, the sampling is progressively less direct. The farther one goes in assessment from a direct sampling, the greater the inferential leap necessary to relate test content to job content. Where shall we draw the line? How far can we go and still claim to be sampling the content of the job? For the present, I will say only that the greater the inferential leap required, the less relevant content validity is in assessing the job-relatedness of a test; that is, the domain being sampled validly is a less satisfactory definition of the *job* domain.

I have argued that a measure can be described

³ In the *Griggs* decision, the Supreme Court has said, "What Congress has forbidden is giving these devices and mechanisms controlling force unless they are demonstrably a reasonable measure of job performance." At first glance, in the context of this discussion, the quoted phrase might be interpreted as requiring content validity. This is an unreasonable interpretation. One cannot "measure" job performance among applicants who have not yet performed on the job. One can *predict* job performance, or one can measure performance on tasks that are samples of the job. Either of these is a job-related use of tests and probably satisfies the intent of the phrase.

Figure 4. Scatterplot: prediction of speed of performance from arm length.

as valid and still not be job related. I will also argue that a requirement may be job related even where the measurement concepts of validity are not applicable. The usual example of a bona fide occupational qualification, the requirement that the men's room attendant be male, may soon be archaic, but I think it illustrates the point.

Certain educational requirements may also be job related even where the validity of inferences as described in the *Standards* is not especially relevant. Consider only one example: the requirement of a degree in mechanical engineering for one who is to design heavy equipment. Possession of the degree does not reflect any homogeneous construct. Its content validity for a job-content domain is probably low; it includes performance in nonengineering subjects, many of the engineering subjects studied may be irrelevant to the particular job, and many aspects of the job may not have been reflected in the work toward the degree. In short, the knowledge and skill required to obtain the degree is a sample of a different domain from that of the job. Yet, personally, I would consider a degree in engineering related to the job of designing heavy equipment.⁴

When I say this, I am implying a hypothesis that people with the degree are more likely to be able to perform the required tasks than are people without the degree. This is a testable hypothesis, but the interests of society are not well served by hiring a lot of nonengineers to design heavy equipment just to do a criterion-related validation study.

Moreover, the logic of the hypothesis seems so clear to me that I would accept the requirement as job related without any further evidence of the validity of the hypothesis.

In short, I view job-relatedness as the extent to which the hypothesis of a relationship between the hiring requirement and job behavior can be accepted as logical. If there are gaps in the logical arguments, or if it is based on weak assumptions, then evidence of validity may be useful to support claims of job-relatedness. But validity and job-relatedness are not the same.

Values in Valid Hypotheses

Job-relatedness is, of course, a digression from the implications of the *Standards*, so let me return to the main theme.

If we recognize that most criterion-related validation is actually the validation of hypotheses arising from real situations, then we must also recognize the influence and nature of the values implied by the hypotheses we choose to examine. If we examine values carefully and if we take them seriously, we may change the hypotheses to be tested. Look again at the packing study.

If we really value speed in packing cartons, we should consider something other than raw validity coefficients. I am sure it has occurred to you that there is something else to consider. Arm length is a valid predictor, but it may also be discriminatory against some women, who, being shorter than men, have shorter arms. Now, discriminating against women may be illegal, but in itself it does not violate our production value unless it also reduces

⁴ This is not a general endorsement of educational requirements, many of which are highly questionable.

the speed of packing golf balls. Figure 4 shows the scatterplot of arm length against packing time. Solid dots represent data from males; open dots represent data from females. The right-hand part of the chart represents mainly men, the left mainly women, and the composite yields a higher correlation than either because of the increased variance. In a sense, the predictor variable is sex. Arm length, however, is a valid predictor only for women, not for men. Figure 5 presents the regression lines from the same data: Tall women are discriminated against when the composite regression line is used.

It is time to level with you. The packing study is a laboratory project in which golf balls were fed by gravity into a tray 32 inches from the subject's seat. For most men, reaching the tray presented no problem; for most women it was quite a reach because we planned it that way. The study was repeated with the tray brought closer: 24 inches. Figure 6 shows that the situation was reversed; for men with long arms, the work space was too cramped for fast packing. Arm length became a valid predictor for men. For women, the "test" of arm length had no validity.

The project was intended mainly to point out two things. First, despite the adverse impact, a silly arbitrary predictor can be valid and its use probably legal. Second, if an employer in such a situation genuinely valued improved performance more than his managerial prerogative to test, he would develop alternate hypotheses and design the validity out of the job. The validity study would be used, not as a basis for selection, but as information about the criterion. If performance is dependent on arm length, then the tray can be set at

an optimum distance for each person, male or female. And for the redesigned job, the "predictor" is no longer valid.

Validity and Values in Other Areas

It would be tempting to stop now if I were not afraid that people would misunderstand. People might think I have been talking about employee selection; I have *not* been. I have been talking about the problem of assessing validity (a) in measuring things we value and (b) in the hypotheses we pose for explaining them. Consider some rather different measurement areas.

ORGANIZED CLIMATE

First, consider that construct, or family of constructs, known as organizational climate. It is generally hypothesized by students of the subject that changes in the climate of an organization will produce changes in such value-laden variables as organizational stability, productivity, satisfaction, and the like. The testing of these hypotheses requires valid measurement on both sides, but let us skip nimbly past the tiresome criterion problem and focus only on the measurement of the climate. In fact, let us narrow the problem a bit more and specify that we shall discuss measurement of perceived organizational climate.

As some of you know, I have argued that perceived organizational climate only pretends to be a new construct when it is really only the rediscovery of the job satisfaction wheel (Guion, 1973). According to Schneider (1973), that is not necessarily so, even if generally true at present. According to his analysis, the perception of organizational

Figure 5. Regression lines in original condition.

Figure 6. Regression lines in redesigned task.

climate is the result of concept formation; it is cognitive in nature. In contrast, the perception of job satisfaction is affective—an interpretation of the perceived environment in terms of the individual's own values, needs, or desires. Job satisfaction is a highly personal, subjective construct; different people react to the same organizational stimuli with different kinds and degrees of affect. Organizational climate, however, should be consistently perceived by different people; it is more objective. Climate is an organizational characteristic; satisfaction is an individual characteristic.

Suppose we were to take Schneider's distinctions as a starting point and develop a descriptive measure (or set of measures) of organizational climate. In the light of the concepts of validity, how should we proceed?

First, we should define a *content* domain. Since we plan to differentiate two constructs, content domains should be defined for each. The content of organizational climate must be defined as possible objective, cognitive descriptions of aspects of the work environment, such as what leaders do. The corresponding content domain of job satisfaction must be defined differently as possible affective reactions to various leader behaviors. When the domains have been defined, elements of these domains can be selected for measuring each construct. If the sampling is done well, both instruments, one for measuring climate and the other for satisfaction, should be judged satisfactory in content validity. (Incidentally, although I am thinking largely of questionnaire construction, other types of measurement could be derived from the same

beginnings. For example, interviewer or observer checklists could be prepared and evaluated in the same way.)

This content sampling does not, of course, say much about construct validity, but it is a fairly good start. The next step should be an item analysis, based in part on item variances. Items describing organizational characteristics should, according to Schneider's construct, have low variances; items describing individual attitudes should have high variances. Conventional analyses should also be done so that internally consistent subscales can be formed for both climate and satisfaction. The climate scales should yield scores for each organization; the satisfaction scales should yield scores for each person.

The product is an instrument for measuring organizational climate for which preliminary evidence of construct validity is accumulating from the manner of its construction and from its demonstrable independence from a valid measure of a competing construct, if that should be the case. Investigators would then develop a network of experimental and correlational studies, including criterion-related validation, to test hypotheses suggested by the theory of organizational climate. If all goes well, the results may both modify ideas concerning the nature of organizational climate and provide further evidence of construct validity. In the process, the validities of various hypotheses about the correlates or effects of climate variables would either be supported or refuted, and these results would carry much greater weight in theory and in practice than would results based on measures of less well established validity.

Let us move to a different measurement problem, one from applied experimental psychology. In 1954, Fitts sought to apply the concepts of information theory to psychomotor performance. A simple task was devised, as diagramed in Figure 7, where the subject was asked to tap alternately two target areas with a stylus. The width of each target area was always the same, identified as W . The amplitude of the required arm movement was identified as A , the distance between the midpoints of the two targets. An index of difficulty was defined by analogy to the information measure using the formula $ID = -\log_2(W/2A)$.

The question of construct validity should be asked about such a measure. Data were reported that support an interpretation of this as a valid measure of difficulty, but as far as I know, the validity of this as a measure of information, as the construct has been defined in information theory, has not been investigated.

Another effort to measure the information content of a job, and more particularly of worker capacity for processing information, is reported by Standing (1971, 1973). Working directly from N -gram analysis (Attneave, 1959), Standing developed a measure of the amount of information in the sequences of operations in an inspection job. No validity information was obtained, but he demonstrated an approach to measuring the information content of work. In the same study he developed a measure of cognitive complexity for individual inspectors, that is, a measure of individual differences in abilities to codify and process the information in the job. The results of his investigation give tentative support for a judgment of construct validity, but there is as yet no network of support.

Uncertainty, or information, as a component of a job or display, and the cognitive complexity of which individual workers or perceivers are capable, are important constructs to people in human engineering, consumer research, job or system design, task simplification, job enlargement, or job enrichment. The motivational hypotheses derivable from information theory seem to have unusual potential for industrial and organizational psychologists and for the states, processes, and outcomes they value highly. Unless we have valid measures of these constructs, however, the best we can offer is idle speculation.

Figure 7. Schematic diagram of the task used by Fitts (1954).

OTHER MEASUREMENT PROBLEMS

Let me mention without comment some other constructs of interest to us for which our measures are often valid more by proclamation than by investigation: cognitive strategies, competence, creativity, effort, equity, expectancy, growth, leadership, long-term memory, obsolescence, organizational stability, productivity, utility, valence, work values.

Conclusion

I do not mean to imply that the whole of psychology or even the whole of industrial and organizational psychology must work with hypothetical constructs and develop evidence of validity for all measures, experimental conditions, or interventions. Quite the contrary. Just as I believe that an employment requirement can be job related without being also described as valid, I believe the science and practice of psychology can be advanced in some situations by behavioral manipulations, environmental changes, or social interventions for which the concepts of the validities of measurements are as irrelevant as they are for measures of arm length. But I also claim that nearly every branch of psychology entertains problems involving the creation of scientific or technological constructs, that measures are and must be derived for such constructs, and that the ultimate worth of the enterprise does in fact depend on the validity of inferences drawn from such measurement.

It is rather peculiar that it is fashionable from time to time to disparage psychological testing, yet many critics of testing often condone or commend work done with measures never subjected to such rigorous scrutiny as is required in the development

or use of a published test. They draw lovely pictures or diagrams and call them models, fill the models with terms they cannot operationalize, and give never a thought to the validities of the operational definitions they *do* use. Much of our field is long on numbers but short on measurement.

It is time for industrial and organizational psychology to rediscover its heritage. The field was built on excellence in measurement. Now, many of us are not particularly excellent. Two important new enterprises—new windows, if you like—are being opened by our brethren in educational psychology. One of these is the content-referenced measurement of mastery, greatly important in personnel applications. The other is the measurement of change or growth in the evaluation of the effectiveness of programs. Few things are more important than program evaluation to those who institute formal programs or speak of their “interventions.” If one is going to intervene, his obligation is to find out whether that intervention has helped or hindered the organizational enterprise. We must not only again give measurement its respected place within our specialty, but we must demand that the standards of effective measurement also be respected. We must stop the sophomoric “naming fallacies” that hide the rediscovery of old wheels behind the rhetoric of new labels. In industrial-organizational psychology and in psychology generally, we must identify more clearly than ever before the dependent variables and outcomes we value fundamentally.

We must often open new windows and travel new highways to find these outcomes. But we must not fall victim to the notion that every change, every innovation, every bright idea moves us closer to cherished goals. Every new highway we travel deserves and needs to be explored with the same thoroughness a test developer is expected to use in exploring the validities of his test. The so-called “testing standards” are in fact standards of effective measurement for nearly all of the directions psychological research might take.

Paradigm Regained?

Cognitive Behaviorism Restated

C. ALAN BONEAU *American Psychological Association*¹

Strategies of dealing with theoretical problems as well as other games psychologists play change as abruptly and as completely as do their tonsorial styles and other displays of individual adornment or behavior. For example, one can only be impressed by the clusters of specialized research problems that arch gloriously through the higher intellectual atmosphere of scientific meetings and then like the Nehru shirt fade away to remain only in the memories of a few.

Such game-playing behavior may have a fadlike quality to it. As in other facets of life where one stays *au courant* by learning the latest dances or dining at the newest restaurants, the psychologist discusses the latest passing theories and performs the newest form of experimental manipulation controlled by the most up-to-date electronic esoterica. In playing games, however, considerable technical skill may be acquired for future reference and application.

Paradigms, to use the handy concept of Kuhn (1970), modulate such transients on the historical time line. Paradigms are more or less encompassing. Those with less ambitious, more limited viewpoints seem currently to have a higher probability

of survival for a reasonable period of time. Such a statement, itself, is a time-bound generalization, but most current perspectives deal with only a very limited range of psychological phenomena.

The 40-year period ending in the fifties, however, was an era of theories of epic proportions (or pretensions). This Wagnerian period of psychologizing produced such heroes of behaviorism as Pavlov, Thorndike, Watson, Tolman, Guthrie, Hull, and Skinner, all concerned with observable behavior as the basic data of their science. Ideations, thoughts, and mental or cognitive structures were the themes of another theoretical mode. The Gestaltists—Wertheimer, Köhler, and the rest—and Freud, like the behaviorists, were gifted heroes and their theorizing was monumental.

Well, as we all know, the age of the antihero is upon us. Even for those of us who would preserve just a smidgeon of that magical aura once a prime ingredient of the dignity of kings, the honesty of presidents, and the infallibility of popes, this is probably just as well in psychology. The conceptual foundations of many theoretical frameworks rested only on the shifting sands of time.

As a result of complex factors, the epic version of psychological theory is no longer the force in psychology it once was. Recent theorists have been content to deal with minitheories, particularly in view of potential devastation should they attempt to be too elaborate. Koch's (1954) treatment of Hull is a case in point.

One possible exception to the historical generalization expressed here is the form of behaviorism espoused by one of the few extant epic heroes, B. F. Skinner. Operant conditioning as a technical procedure and behavior modification as an applied technique have achieved unprecedented renown for psychology *qua* psychology. The Skinnerian viewpoint, however, is myopic about a good deal of the material others would like to consider to be psychology. While the textbooks written by eclectic

¹ The author is Director of Programs and Planning of the American Psychological Association. The ideas were developed and the article was written over a period of a few years when it was possible to take annual leave from APA for a few weeks or a day or two here and there. Special thanks are due to the State of Maine for its rockbound, uncrowded coast; Ann Boneau for typing several generations of what turned out to be a family project and giving up otherwise good vacation time to boot; and James L. Cole, who was in on it when it all started but was prevented by other pressures from involvement in the development. The author is deeply indebted to the anonymous reviewers who provided several useful suggestions that have been incorporated into the article. The views expressed in the paper should not be construed as representing opinions or policies of the APA.

behaviorists and others often seem a hodgepodge of unrelated subject matter on which psychologists happen to be working, the Skinnerians achieve a conceptual purity (and strength) by ignoring selectively much of the subject matter of psychology. They aver implicitly if not explicitly that such subject matter is unimportant or perhaps not even psychology.

Skinner aside, there are advantages to major frameworks, the perspectives or paradigms that relate to one another the major pieces of a science. The interconnections among the pieces become visible; prerequisite skills to enhance understanding are made apparent; strategies for teaching the discipline as a whole are evolvable; the material becomes easier to learn when it ties together; the important is delineated from the trivial; the field becomes easier to understand and to use as a basis for advancement of knowledge. In retrospect, some obvious substantive advances may fall quickly and simply out of fresh paradigms, or complex formulations may become simplified.

The author feels that these constitute good and compelling reasons to attempt periodically to advance a formulation epic in comprehensiveness. Psychology as a science has grown enormously in technical sophistication. There exists a sizable amount of simple advance polished piece by piece by a number of highly skilled and creative individuals. What is needed is a schema to utilize this material as basic building blocks of a coherent structure.

A few years ago, the author (Boneau & Cole, 1967) presented a theory to account for the behavior of pigeons making a discrimination among various spectral wavelengths. That theory utilized statistical decision theory concepts and posited that the pigeon internalizes and uses information about the outside world in the process of discriminating. The information used by the pigeon in the original formulation was limited to hypothetical processes underlying only a limited range of behavior. Subsequently, the author has generalized the formulation to include a broader range of behaviors. This generalization is presented in this article.

Initially, this impulse toward conceptual expansion was fueled by the recognition that the language system of the formulation had certain advantages over traditional behavioristic language. While behavioristic approaches tend to imply that behavior is under external control, as expressed in the widespread use of the term *stimulus con-*

trol, the decision-theory/information-processing approach, on the other hand, seems to imply that behavior is determined primarily by events within the organism and permits behavior to be based on cognitive processes of various kinds. Thus, the information-processing approach allows for an approach to the intuitive conception of the layman of personal responsibility and involvement in production of his own behavior.

Further, the decision-theory/information-processing approach to traditional, behavioristically formulated problems provides the possibility of building a bridge between such areas as operant conditioning and information processing, both of which had been developing in experimental psychology relatively independently of each other. As clarity emerged in the evolution of the formulation, it became apparent that additional gains flowed from it. The formulation illuminates some psychological conceptual areas, provides the working psychologist with greater capability for analyzing basic processes, suggests directions for further research and application, and tends to tie together widely diverse areas of psychology.

First, the conceptual scheme based on information-processing notions will be described, including a discussion of the variables of which behavior is assumed to be a function and the way they combine to produce behavior. Then to illustrate the value of the approach, there will follow an explication of the way in which the formulation can be applied to several processes that are considered generally to be psychological in nature. As we proceed, we will indicate how the many areas of psychology can be related by virtue either of their contribution to the understanding of the workings of the information-processing system or by the light shed by the system on other areas. Finally, we will attempt to evaluate what the framework accomplishes for us.

The Theoretical Framework

The theory assumes that, through extended commerce with the environment, the individual internalizes information about the external world. We start with a discussion of the internalizing process, with its structure and how changes in the structure and its content occur. Following that development, the way in which this internalized information is combined with information about motivational states to determine behavior will be indicated.

The internalized information is assumed to be structured into an *internal model of the environment* (IME). The IME is unique to the individual and is based on the individual's history of interaction with the world and with biological potential in a very personal way. The IME depends on the external world, but it is not necessarily a veridical representation for a number of reasons that will be spelled out as we proceed.

The theory identifies three dimensions of the IME that correspond roughly to the external dimensions of stimulus, response, and reinforcement with which S-R formulations deal. In this account, the three dimensions will be called *situation*, *action*, and *outcome*, each of which may have objective external observable manifestations in addition to the internalized version. To distinguish between the external and internal versions of these events requires a special symbolism. In what follows, the external or veridical situations, actions, and outcomes will be designated by the capital letters *S*, *A*, and *O*, respectively. The internal correspondents will be designated by the small letters *s*, *a*, and *o*, respectively. When necessary, subscripts will be used to differentiate between different occurrences of events on any of the dimensions.²

Let us consider the situation dimension first. The processes by which external physical energy is transduced through the sensory receptors of an organism and subsequently segregated and organized is the subject matter of important chapters in psychology which are relied on here. For example, all the rich panoply of visual stimulation are available as potential information in this process. Faces, symbols, colors, places, things discriminably different from other similar things are the basic situational events that become processed into the internal model of the environment. As general psychology has demonstrated, the individual has the capability to perform the appropriate perceptual activities to accomplish these remarkable differentiations and constructions.

There are a large number of physical dimensions along which external events can differ, of course, many of which have corresponding internal variation. The way in which organisms can come to respond differentially to small changes in external stimulus dimensions is important for the understanding of the total process. For our purposes here it is sufficient to note that any discriminably distinctive aspect of the total array of potentially internalizable stimulus dimensions or combinations of dimensions can form cues that are the elements of our information-processing system. The fact that individuals can learn to differentiate between similar situations is basic to the theory.

To be sure, we are finessing the epistemological problem of distinguishing external from internal reality by taking the position of a naive realist. Things, we assume, are "out there," and, further, they are what they seem to be at least most of the time (even though we know them only phenomenologically or inferentially).

A second dimension of the IME consists of actions. The way in which individual muscle twitches, nerve fiber firings, and gross muscle movements are coordinated into organized sequences is again the content of other chapters of psychology. In this account, actions do something. The somethings can consist of looking at, of walking, of performing specific kinds of movements, and the like. It is taken for granted that responses are coordinated into integrated greater wholes of movements that may with practice become skilled movements. All such integrations of behavior whether skilled or unskilled are elements in the action dimension. The fact that movements become more precise and skilled with practice has significant consequences for understanding their role in the overall behavior of the organism. This will be discussed later.

The internal action dimension is conceived of as an internalized list of potential actions that can be brought into play by the individual. For organisms such as man that have a capability for extensive manipulation of symbols and images, elements on the internal action dimension need not correspond to actions that have been performed by the individual. Rather, for registration on the action dimension, it may be sufficient to observe the actions of others or even to conceptualize new possibilities of actions that have been performed by no one. We assume in dealing with lower organisms, however, that such ability is limited and that the in-

²The SAO terminology was utilized earlier by Irwin (1971) in a different formulation. The reader is referred to his book for discussions of several conceptual issues that arise in "cognitive" theories in general and are very germane to the present one. What is meant by a cognitive theory in the sense intended here seems implied by the definition of "cognition" proposed by Neisser (1967): "The term 'cognition' refers to all the processes by which the sensory input is transformed, reduced, elaborated, stored, recovered, and used [p. 4]."

ternal action dimension consists generally of internalized representations of externally observable actions that have been previously performed by the organism, or have been programmed into the behavioral repertoire as innate or instinctual givens.

The third aspect of the IME consists of outcomes. Outcomes are thought of as sensory inputs and thus essentially the same dimension as situation. It is convenient, however, to view outcomes as changes in situation correlated with or contingent on actions, although lack of change in situation following an action is no less an outcome. In the real world, outcomes are such things as the food pellets that follow a bar press by a rat. To the rat, the outcome is information about the occurrence of the pellet—that a change in situation has occurred with all of the associated sounds, sights, smells, and tastes that constitute the events of the internalized outcome dimension. As with other situational events, we assume a capability of the organism or individual to isolate, identify, and otherwise perceive changes in situation as outcomes and as correlated or linked contingently (whether real or imagined) to actions or other situational events. An important class of outcome inputs are those that arise from internal stimulation, for example, visceral reactions.

The basis then of the formulation is that the individual internalizes, that is, extracts information about the outside world and about his relationship to that world and constructs an internal analogue of critical portions of that information. This information can be about external situations in which the organism has found itself, actions that the organism has performed, and outcomes correlated with actions or situations. What the organism learns and what is internalized is information about when, where, and how outcomes are available. For outcomes that the organism has experienced, the internal model of the environment contains information about the actions that produce these outcomes and under what conditions. But the above statement about the information is not sufficient. It does not yet have built into it information about the uncertainty that outcomes will follow actions. Most such relationships in nature certainly are not invariable. We now examine this complication in more detail.

Let us choose probability language to denote the uncertainty. A complete description of the external world (heaven forbid!) would consist of the complete set of probabilities that all possible out-

comes will occur under all possible combinations of situation and action, namely, the set of all conditional probabilities P_{ijk} , where $P_{ijk} = P(O_i|A_jS_k)$, that describe the probability that outcome O_i will occur given that action A_j has taken place in situation S_k . Stated so baldly, a complete description is a technical and theoretical impossibility.

For analysis, it is useful to restrict the SAO space to a limited number of possible combinations, a procedure adopted by the science of psychology to focus on the relatively pure case. Outcomes can be arbitrarily limited in equipment such as the Skinner box to, say, a food pellet sliding down a chute to the hungry animal (O_1) or no food pellet (O_2). Effective (or countable) actions can be limited to a deflection of a right-hand bar (A_1) or a left-hand bar (A_2). Situations can be restricted to the presence (S_1) or absence (S_2) of a light in the side of the box.

Also defining the "external world" constructed by an experimenter are the conditions under which outcomes are related to action and situation. An example might be in the form of a statement that the animal will receive a reward on a random 50% of bar presses on the left-hand lever only when the light is on; otherwise no reward is forthcoming.

Under this limited set of conditions, the "veridical world" of the experiment is defined by the probabilities P_{ijk} as follows:

$$\begin{array}{ll} P_{111}(O_1|A_1S_1) = .00 & P_{211}(O_2|A_1S_1) = 1.00 \\ P_{121}(O_1|A_2S_1) = .50 & P_{221}(O_2|A_2S_1) = .50 \\ P_{112}(O_1|A_1S_2) = .00 & P_{212}(O_2|A_1S_2) = 1.00 \\ P_{122}(O_1|A_2S_2) = .00 & P_{222}(O_2|A_2S_2) = 1.00. \end{array}$$

A careful study of the set of probabilities shows that the only time the food pellet (O_1) occurs is in conjunction with left lever press (A_2) when the light is on (S_1), and the probability of that occurrence is .50. Of course, with a probability of .50, O_2 occurs with A_2 and S_1 , or if you prefer, O_1 does not occur.

The above provides a succinct description of the salient features of the external, "real" world as they apply to our formulation. What about the internal version, the IME? According to the formulation; internal representations of the P_{ijk} are built up over time as the animal "learns" the task: the situations, actions, and outcomes. This requires among other processes mentioned earlier a probability-estimating mechanism to permit the development of internal states that we will call internalized or subjective probabilities. These shall

be designated p_{ijk} to distinguish them from the external, experimenter-determined values, the P_{ijk} .

As a result of these considerations we can now describe the IME to be composed of subjective conditional probability elements and define them as $p_{ijk} = p(o_i|a_j s_k)$. One form of learning consists of modifications in the p_{ijk} with increased experience so that they may come to approach the P_{ijk} in value. A well-trained animal, for example, with long, appropriate experience, may behave as if the P_{ijk} and the p_{ijk} have identical values. That animals can do this kind of learning is well documented. See, for example, Estes (1957). Human individuals are no less capable.

There are a number of obvious distinctions between the IME and the external world itself. First and foremost, they are different versions of the same thing and in fact may not even be similar. Consider the fact that the experimenter may suddenly change the required response to be a press on the right-hand lever instead of the left. At that point the characteristics of the "real" world are rather drastically changed, but it may take considerable experience by the rat in the situation to have the new state of the real world reflected in the IME and in behavior. The IME may, in fact, never recover from such an experimental manipulation and continue to have a residual positive probability value attached to left lever presses.

In another way the IME may not accurately reflect the real world. The IME, as conceptualized here, is based entirely on the outcome history of the individual. If for some reason the individual has not performed a response necessary to achieve a potential outcome, the IME will be less articulated than the real world. Potential actions may have no internal counterpart. If the animal when placed in the box never presses the lever or does not press it hard enough, there will be an incomplete internal representation of the potential for action in the situation.

The IME also may not be a useful representation of the external world if the situation requires fine discriminations among situations as a basis for outcome differentiation or requires skilled performance of certain actions. Ignoring the discrimination or performing the action clumsily may prevent the occurrence of desirable outcomes. As a result the individual's IME is less developed than it could be or may have zeroes when the actual probability for a desired outcome is greater than zero.

In our numerical example, the stimulus light may in fact have two physically similar intensities, one of which (S_{1a}) is always reinforced, the other (S_{1b}) never; but they occur equally often. Unless the rat has had a history of experiences in which subtle differences were important, the discrimination may not be made and the IME will not reflect the realities of the situation.

In a very brief way, the above has been an attempt to describe the basic elements on which behavior is based according to the formulation unfolding here. There is a strong flavor of the purposive behavioral approach of Tolman (1932), and the IME of this formulation must bear a familial resemblance to Tolman's "cognitive map" (Tolman, 1948).² Likewise the p_{ijk} 's constitute a more precise way of conceptualizing "sign-significate relationships" or "expectancies." There is more, however, to the present formulation than "mod" clothing. The conditional probabilities allow the use of further machinery to push past conceptual shortcomings of the Tolman approach. Tolman's theorizing, for example, provided no easy way to prod the individual into action, and, according to Guthrie (1952), left the animal "buried in thought." The present formulation provides an axiomatic solution to this problem; the details are discussed next.

Outcomes often have connected with them another extremely important aspect that is essentially motivational in nature. That aspect is characterized by sensations of pleasure or pain and has been variously called *utility*, *value*, and a host of other names by various writers. We will call it *hedonic value* (or sometimes, for short, simply *value*). We note in passing that an outcome and the hedonic value associated with that outcome are considered to be independent, separate aspects processed as distinct items of information. The need for this distinction is that hedonic values of outcomes may change for a variety of reasons important for the theory but occasionally psychologically trivial, for example, the diminution of the value of food because of eating.

We assume that hedonic value can be measured on a unidimensional scale. For our purposes, we further assume that all outcomes can be measured against the hedonic value scale, that combinations

² Tolman's theorizing and extensions from it that have similarities to the present formulation are discussed in Hilgard and Bower (1966). Others seem to be closing in fast. See, for example, Mischel (1973).

of value occurring at the same time are combinable on this scale, and that the individual *can* make absolute value judgments. The scale we assume, for convenience, to range in both positive and negative directions with a zero point. The requirement of a zero seems not necessary, and the scale can be treated as dealing with relatively ordered preferences. (For example, see Premack, 1971.) For expository purposes, however, it seems useful to consider positive values as associated with attractive outcomes; negative, with repellent outcomes; and zero values, with neutral outcomes. (See also Irwin, 1971.)

The hedonic values of outcomes as we have noted are not necessarily fixed. The value of food-related outcomes, for example, increases with hunger. Also, as with olives and chamber music, one's values associated with outcomes can change through a learning process presumably involving learned emotional responses. How values have the value they have and how they change is another whole chapter of psychology. The value-outcome structure of different individuals seems to be primarily based on their classical autonomic conditioning history and is a significant factor contributing to individual differences in behavior. Hedonic value, thus, is dependent on time and should have a time (or trial) subscript. Usually for convenience, we will drop the time subscript. Hedonic value, of course, can also be highly determined by unlearned factors; for example, the value of a sweet taste is apparently a built-in hedonic operator for many species.

Hedonic value determines behavior in a straightforward way. Let us assume as an axiom that the individual will behave in order to maximize the potential hedonic value available in a situation. This is fundamentally a statement that defines a characteristic of human (and animal) nature. It is by no means new. Historically, versions of utilitarianism have been outcroppings of a pervasive stratum of philosophical thought.

It should be noted that the axiomatic nature of the assertion makes it a tautology. If behavior appears not to maximize utility, that, by definition, is a fault of the observation. Because the behavior is maximizing something by definition, it behooves the observer and/or analyzer of behavior to identify precisely what is being maximized. This feature of the theoretical statement is the basis for a conclusion that the statement is not capable of

being disproved. Whether the statement is useful is the topic of this article.

How may we stipulate a procedure by which the individual determines which action to perform in order to maximize the potential hedonic value? Outcomes are not all equally probable, so we may use the conditional probabilities in the IME as weights to produce *expected* hedonic values (in the precise probability sense of that term) by multiplying the p_{ijk} 's by the values. Since outcomes are contingent on actions, we associate hedonic values with the actions associated with them. The expected hedonic value h_j associated with action a_j , for example, will be the hedonic value of outcome o_i multiplied by the probability that outcome o_i will occur if action a_j is performed in situation s_k , or

$$E[h(a_j)] = h(o_i)p(o_i|a_js_k).$$

Actually, in a situation any action may have several outcomes with different probabilities and varying hedonic values associated with them. For example, a bar press may sometimes result in a large amount of food with a high momentary hedonic value to a hungry animal. A smaller amount of food may occur with a different probability, and no food, on its own probability schedule. All bar presses require a certain amount of exertion which will have a relatively negative hedonic value. The expected hedonic value of the bar press (action a_j) for a given situation then will be the sum of all expected hedonic values of the outcomes associated with the action, assuming them to be additive, or

$$E[h(a_j)] = \sum_i h(o_i)p(o_i|a_js_k).$$

The maximization axiom requires that the expected hedonic value of actions available be evaluated and the action be performed that provides the maximum, that is, the action a_j corresponding to

$$\begin{aligned} \max [h = f(a)] &= \max E[h(a_j)] \\ &= \max \sum_i h(o_i|a_js_k) \end{aligned}$$

for all a_j and fixed s_k .

To recapitulate, potential payoff in a situation can be represented as the sum of the expected values of all outcomes associated with each available action represented in the IME. The behavioral axiom, at that point, requires that the action be performed for which the summed expected value is greatest. In a more precise way, we may state

the maximization axiom as follows: *In any situation the individual will maximize the expected hedonic value by performing that action which produces the set of outcomes for which the summed momentary subjective expected value is the highest.* It is momentary expected value because values may change over time, and it is subjective because it is based on the idiosyncratic, subjective, internalized conditional probabilities of the IME. "Highest" in theoretical terms means highest in numerical value or its analogue (but behaviorally and tautologically it means "most preferred").

Summarizing the whole theoretical machinery, it is supposed that the individual through commerce with its environment can create for itself a model of that environment containing information about known situations, about the set of known outcomes available, and about the likelihood that those outcomes occur when known actions are performed. The theory then postulates that the individual in any situation evaluates the set of possible outcomes with their various hedonic effects at that time, determines the expected hedonic value of the outcomes, and then performs the action necessary to produce the highest expected hedonic values.

This general formulation of behavior, as we have noted, was developed for a particular experimental situation by Boneau and Cole (1967) to apply to the behavior of pigeons in a color discrimination task in a Skinner box. In that application, the critical elements of the IME consisted of situations defined as points on a hypothetical dimension of hue varying according to a Thurstonian dispersion process; key pecking and no key pecking were actions; a known amount of grain and a fixed effort for key pecking were outcomes; and the internalized probabilities of reward, given each situation, were presumed to approximate veridical values for the pigeon after several thousand trials. The proportions of pecks to variously closely spaced monochromatic spectral stimuli were used as estimates of the proportions of times that the expected hedonic value for pecking was greater than the value for not pecking. By inference these estimates could be used to determine parameters of the hypothetical Thurstone discriminial processes. The reader is referred to Boneau and Cole (1967) for details.

Applications

The remainder of this article has a number of goals related to an exploration of the utility of the global,

epic approach, and particularly to the formulation presented here, in thinking about psychology. First, the structuring of the field of psychology from the point of view of the formulation will be considered briefly. The formulation is seen as a device that allows for the viewing of psychology as a coherent, organized panorama rather than as a collection of disparate intellectual and scientific doodles valued as a whole only by those either with sufficient faith or with a highly developed appreciation of abstract design to support a belief that it somehow all makes sense. To emphasize the scope of the approach, there will be a discussion of phenomena in behavior modification at some length and a very brief discussion of thought processes.

Let us try our hand at the big picture and how pieces of psychology relate to the system and each other. One emphasis of the IME is its focus on input and output relationships between the organism and the environment. We have seen earlier how subareas of sensation and perception and further refinements in those fields are essential to an understanding of inputs to the system and to give substance to the situation and outcome dimensions.

Likewise, the dimension of action is one that has been intensively studied, particularly in applications where the problem is one of skill learning. The whole subfield of action is broader, involving the many ways that the potential for action is internalized in the IME. For example, trial-and-error learning, observing the behavior of others, being instructed, maturation, instinct, and motor coordination differences all play a role in the understanding of actions as they relate to the IME.

The mechanisms by which contingent probabilities are acquired have been a major concern of mathematical learning theory and Bayesian approaches, among others. Including these areas as additional contributing factors to the understanding of behavior fits a few more pieces into the emerging picture. Adding the subfields concerned with motivation, with the processes underlying innate and acquired values, fills out the basics of the theoretical approach. Physiological processes related to depression or anxiety seem important here. In fact, selected portions of the biological substrate are essential parts of the curriculum and can be introduced as appropriate.

A curriculum designer might construct a cycle through the general concept of the IME and maximization notions and then iterate back through the

more specialized areas to provide depth to the conceptualization. It would be appropriate to include neurophysiological formulations insofar as they add to the understanding of the basic processes. A curriculum structured in this fashion would have much the same kind of hierarchical structure as does physics, for example, and prerequisites would indeed be in order to provide a more in-depth understanding of the five processes.

The areas of psychology dealt with above certainly do not exhaust the intellectual domain of psychology. As we have presented these areas, however, they have been propaedeutic to the understanding of the workings of the basic system. Other areas may be seen as derivative processes emerging from the functioning of the system.

Consider, for example, the pattern of persistency of life-style and behavior that psychologists call "personality." The explanation offered by the present formulation goes as follows: As the individual develops, some actions are found to maximize hedonic value because of individual aptitudes or personal characteristics, or because the environmental context, including societal and personal relationships, provides outcome supports for some actions and not for others. These selected actions become more successful over time in increasing payoffs as skill develops and as subtleties of the situation that signal variations in outcome are discriminated. The individual becomes relatively masterful in negotiating the range of situations and actions accessible in a particular life-style and thereby relatively less masterful in dealing with the congeries of situations and actions that characterize other life-styles. It becomes maximizing then to limit oneself to the range of situations and actions with which one is familiar and has mastered or made the most of. Life is thus a climb uphill to a relatively maximizing style. Likewise, one is encouraged to make use of previously mastered actions as a means of coping when thrown into new situations, or to look for instances in which well-developed actions may pay off.

It should be recognized that there exist a large number of alternative locally maximizing conditions at least potentially available to each individual. Accidents of situation, parental and other societal controls, abilities, aptitudes, and special supporting or undercutting outcome circumstances including traumatic experiences provide texture to an IME that may lead to commitment to a life-

style that has the property of being self-sustaining if it provides locally maximizing opportunities.

Since maximization of hedonic value implies that the individual will perform actions that have a high probability of producing a valued outcome, the individual may more and more frequently tend to seek situations having high outcome or value potential because action itself may involve mobility toward situations conducive to reward. At the same time, the individual may become more capable of differentiating critical elements of the situation and of performing an action whenever skilled or selective action itself increases the payoff. Practice, of course, makes perfect. Moreover, outcomes themselves may through classical-conditioning mechanisms keyed to fundamental drive states achieve a changed associated hedonic value either positive or negative. As a consequence, the individual tends to lock onto particular well-known situations and highly skilled actions that have been determined by experience to maximize known available hedonic value which itself is changed by the complex of circumstances. Any change away from a known source of reward or a new variation in a highly skilled action, almost by definition, is likely to result in a step away from a locally maximizing condition, and thus downhill with respect to expected hedonic value. The maximization axiom does not tend to permit deviation from well-known maximizing actions or situations.

The IME is the individual's own unique view of the world and determines his role in it. Childhood is spent in learning what the world has to offer and what can be done about getting what is available and under what conditions. By the time the individual approaches middle age, under most conditions in our society, the IME has stabilized as the individual becomes situated in a niche that makes use of whatever skills have been developed. The individual becomes hedged in with constraints based on experience about the availabilities of outcomes and the successes of actions. The IME thus provides the consistency link required for a theory of personality and, from the viewpoint of this theory, defines, along with the value system, the personality of the individual.

The temptation, or perhaps the practical necessity, of making first statements overly simplistic must be acknowledged. As Mischel (1973) pointed out, however, there is a considerable amount of lability to be accounted for in addition to consistency for those in the business of personality

theorizing. There is no intention here of insisting on the immutability of the IME, and the system presented here seems to allow room for personality restructurings in addition to moment-to-moment fluctuations. Changes in the external environment, trauma, and the like will undoubtedly produce changes in the IME, and such changes should be included as phenomena in learning theoretical approaches. Under generally *stable* conditions, however, the notions of IME tied in with skill-learning concepts will tend to produce an individual with stable behavior-correcting properties. We also pointed out that *successful* behavior under generally stable conditions can tend to create the conditions under which such behavior is possible.

It is highly likely also that behavior will be subject to ongoing fluctuations in the value of outcomes. Hunger certainly is one example, but other conditions such as mood swings, general anxiety, and the like could create, or are symptoms of, value changes. An understanding of the nature of such states and their causes seems essential to our understanding of personality.

Although the author has not pushed the development, other aspects of psychology also seem derivatives of the basic processes of the hedonistic system. Psychopathology would seem to deal with anomalies of the IME or the utility structure and their interactions. Social psychology properly should in part be concerned with the mutual interrelationships of individual IMEs and other determiners of behavior in a group setting; sociology and organizational psychology, with the interactions between individual IMEs, on the one hand, and institutional constraints and supports, on the other.

In total then, the cognitive behavioral/hedonistic approach seems to provide a home for many of the subspecialty areas of psychology. What else can it do? Consider behavior modification from the point of view of the present formulation. The main contribution made from the translation from behavioristic to cognitive hedonistic language is that the possibility of thinking about alternative action in a systematic fashion is greatly increased. This is partly because there are more specific variables in the new view, and all of the variables are open to manipulation. Let us examine the modification of behavior in some detail.

Given a system that tends to seek self-consistency, how can modifications occur? The answer is that changes can occur in the IME or in the hedonic value structure of an individual and that

these changes affect behavior. Any of the variables p , s , a , o , h may be subject to experimental manipulation. In our terms, the diagnostic technology of behavior therapy involves determining the details of the local maximizing strategies determined by the ecology and history of the individual; defining the available outcome, or behavior support and constraint, structure; assessing the strengths and weaknesses of the individual with respect to discriminative facility for dealing with situations; surveying the range of skills and aptitudes for action; and determining the associated hedonic values of the actions.

Assuming that the individual's current state of affairs is locally maximizing, the task of the behavior therapist is to prescribe a set of procedures that modify the IME so that a different portion of *sao* space becomes a new local maximum. The art of prescription involves choices among alternative local maxima and strategies to attain them. Such choices necessarily are based on ethical and moral criteria, a fact that provides a new set of complexities. Let us examine procedural details from the standpoint of the theory without forgetting this problem.

A change in the IME can arise from a variety of processes or circumstances. Do we know how to create change? In many cases we do. First, the internal situation space can expand through an increase in the number of s_k . This could come about because the physical environment becomes different for some reason, new situations (S_k) added. An old situation may become more sharply differentiated, for example, new aspects noticed or discriminated. One way of causing such a change is by telling the individual what to look for! After all the skilled poker player may have become expert at reading facial expressions as cues to the strength of the hands of his opponents by virtue of learning that such cues are important. Barring permanent amnesias or sensory losses, it is likely that the internal situation-space monotonically increases, except that limitations of processing capacity, for example, attention or memory, may require that portions of the internal situation-space be ignored at any one time. One does not always immediately remember all details of places that have not been seen recently.

Second, the potential for activity in a situation may increase. New things may be introduced into the physical space to be acted on. The individual through explicit or implicit trial and error, or by

observing others, or by being instructed may discover other possible actions in an otherwise unchanged situation. Existing actions may increase in skill and complexity, in vigor, strength, or coordination; or action may itself modify the physical situation, for example, by moving the individual to another location and thus changing the situation's potential for further activity. Athletes and musicians are examples of individuals who capitalize on highly skilled actions, although everyone develops skills of one kind or another.

Third, the outcome set may change. Old possible outcomes disappear and new ones appear. Changes may occur in outcome characteristics. Size, color, taste, quality, consistency—all may vary. The individual may learn to discriminate more clearly among sensory dimensions so that the IME may expand with no physical change. One example is the discriminatory skill developed by the wine taster.

Fourth, the probability of the outcome may vary. This can be due in part to changes in the physical situation: If rewards become scarce, the probability of the outcome diminishes. But probability may be related to the ability of the individual to deal effectively with the situation—to make appropriate discriminations, to perform skilled actions when necessary, and thus to make the most of a situation. The star salesman, for example, maximizes by increasing the probability of a sale through sales tactics directed by an analysis of the customer, all learned by experience. Thus, the individual's own outcome history may depend in a rather direct way on the complexity of his IME.

Introducing new contingency relationships between actions and outcomes is the basis for "token economies." Highly valued outcomes can be made not to occur unless specified actions take place, a state of affairs that is possible in institutional settings containing powerful controlling figures to define contingencies. In the case of the ubiquitous Skinner box, an institution of another sort, there is an all powerful experimenter aided and abetted by his relay rack.

Lastly, the hedonic value associated with outcomes may change. Changes in the physical outcome itself may eventuate in a less desirable reward, for example, if food becomes spoiled. More subtle is the process by which shifts in the acceptability, the preference, the liking for a person, thing, place occur. We are all aware of the potency of the almost unexplainable, occasionally

irrational, often overwhelming determiners of behavior, the emotional attachments, pushes and pulls, that at their extremes create overriding hedonic value influences on the behavior of the lover, the patriot, the saint, the martyr, the escaping prisoner, etc. In more moderate doses these factors contribute to the human quality of human beings, gently but firmly contributing to behavior. Much of the appropriate explanatory chapter of psychology dealing with such motivational matters has yet to be written. It would seem, however, that classically conditioned autonomic responses are implicated at least in part. Behavior therapy notably focuses on such value changes, for example, in desensitization by reducing situationally produced anxiety to specific stimuli. The extent to which positive values become associated with pleasant or nurturing situations is also well known but perhaps too little understood.

The problem of maintaining performance, say, as modified by a token economy procedure, under new circumstances is one that has been noted in the behavior modification literature (e.g., see Davison, 1969). In the present analysis, performance maintenance requires that the modified behavior be maximizing under the new circumstances. Without dwelling on the problem in any detail, let us consider a few of the possibilities. If the individual is changing from an institutional setting to a natural environment (or as is often seemingly the case in modern society, from one institutional setting to another), behavior maintenance will seem to require that the IME and value structure are compatible with the new environment; that is, actions predicated on the IME and value produce a satisfactory level of favorable outcomes in the new set of situations. If the purpose of an institution is to modify behavior from what existed previously, the requirements are a modified IME, a changed value structure, or a change in the natural environment, or combinations of the three such that the specific, focused-on behaviors are maximizing. A separate possibility is a retreat from one natural environment to another that is more supportive of the existing skills and value structure of the individual. We have already considered options open to the manager of change and have intimated that value judgments involving the future of an individual are distressing complications. Perhaps the best solution is to involve the individual in the selection process!

The foregoing analysis provides a large number of factors that provide strategies for analysis and

for the design of action programs in behavior shaping. The possibilities, particularly in combination, are numerous. To change behavior through modifying the IME, one can physically change the situation, or help individuals make more subtle discriminations about the situation and its cue aspects in order to educate the individual about distinctions within and among situations, distinctions that permit a greater understanding that different cues signal different situations. One can provide the individual with other possibilities to action or to improve on those actions he already performs, that is, to increase effectiveness. It should again be pointed out that the IME is in fact a personal construct inseparable from the individual's own situation-action-outcome history. The individual may know that valued outcomes are available for those with appropriate skills, yet realize that without those skills his own personal IME does not include the possibility of the necessary action.

Observing others perform an action of which he is capable may, however, expand the IME. If that action does not produce the desired outcome, then a problem-solving effort may be required to determine what conditions are necessary. *Modeling*, as the process is called, has been shown to be an effective means of transmitting information about possible actions and contingent outcomes to observers. The assumption here that humans can observe the behavior of others and visualize a potential action of their own, or at least incorporate the possible action into their own IME, allows us to bridge what otherwise might be theoretical limitation. While the mechanisms are not yet well known, the phenomenon is well documented. Our analysis implies that in general modeling will work as an "action" for those who have found that modeling the behavior of others has been successful in the past, that is, for those for whom it has had a relatively high probability of producing an outcome with high hedonic value. Individuals with a history of failure at performing observed activities, in particular, would not necessarily follow modeling as a strategy. One has to know appropriate skills to be able to model successfully. Further, the analysis allows us to state that modeling might be adopted in cases in which the model appears "similar" in capabilities to the observer, thus implying a similarity in the subjective probability of an emulated successful action. Models who appear too different from the observer may not contribute to an increased probability that

an action may be relatively effective for the observer himself.

Implicit in the foregoing is the fact that learning cannot be viewed as a single factor from the point of view of this hedonic theory. Learning to differentiate among similar situations is vastly different from becoming adept at some athletic task, although both may depend on the other, and learning to like black coffee is different yet. Tolman (1949) described more than one kind of learning tied to the pieces of his system. The distinctions between kinds of learning in this theory, while similar to those described by Tolman, are based on which of the elements p , o , a , s , h are primarily affected by manipulations. The advantage of the theory formulated here is that it makes explicit the distinctions between several varieties of learning and implies that different procedures should be utilized for inducing changes in behavior, depending on the kind of learning involved.

Ordinary school learning, for example, according to this analysis can be of several kinds. First there are a set of skills or actions such as reading, writing, and arithmetic that make it possible for the individual to participate further in school and thus open up the possibility of participating in a world with an expanded SAO space. Second, there are a whole set of content-oriented subjects such as geography, history, language, and literature that are instrumental in gaining access to the SAO space that is reserved for educated individuals and for sharing in the reward structure associated with that particular SAO space. In part, content learning provides new options to the individual because it can describe and differentiate new situations, actions, and outcomes for the individual. To understand the process of learning for content requires a theory of instruction and rote learning that is in a separate chapter of psychology.

Another form of learning is associated with schools. From the perspective of the present theory, all sorts of actions related to performance in school such as paying attention to teachers, doing homework, concentrating on work at hand, and learning specific methodologies are actions that themselves may under appropriate conditions become maximizing. It is helpful to have parents who maintain a reward system that recognizes school performance and supports it appropriately.

Let us now jump to a consideration of pure cognitive functioning from the point of view of the formulation. We have already discussed the pos-

sibility that reorganizations of IME may occur as a result of a variety of processes in addition to the traditional behavioristic concentration on environmental factors. We have said, for example, that observation of the behaviors of others along with the outcome contingencies are allowable inputs to modify the individual's IME under some circumstances. Individuals indeed have such capabilities. We shall explore other possible capabilities.

Why not, for example, postulate as a form of action the process of implicit trial and error? Such a process could have the individual sort through memory for possible actions not utilized before in a particular situation, making an assessment of the probabilities of outcomes of various kinds. If such trial-and-error actions indeed produce desirable outcomes, the process (or action) of making such hypotheses would itself come to be a relatively maximizing approach to life and lead to an individual who thinks before leaping or performing any other form of action.

We can even imagine a process of internally generating new possibilities for action, of reorganizations of situations, of newly created outcome possibilities. If such a process is successful in maximizing outcomes for the individual, we can imagine an individual whose behavior may become to a degree unpredictable because it is based on an internal process geared to the task of generating novel action, of restructuring the internal environment. We can even imagine that such internal processes may themselves acquire positive value and thus become relatively autonomous. A humanistic version of the human individual emerges as a distinct possibility.

Such a brief characterization of thought processes serves only to whet the appetite. The author has not had sufficient time available to explore the ramifications of the approach in any detail at all, but is intrigued by the seeming fact that thought processes as subject matter and objective behavioral phenomena can be housed compatibly in the same framework. Such a conceptualization may be objectionable to the psychologist who bases his science only on objective forms of behavior. To the psychologist who was trying to include cognitive processes in his psychology, however, the formulation provides a bridge to other areas of psychology.

Conclusion

Despite some of the connotations of a cognitive theory, there is no need to deal with concepts such

as consciousness in order to get one in operation. The cognitive processor need only be a mechanism that categorizes inputs, computes probabilities, assesses values, and makes decisions, a feat that can be accomplished in a simplistic way by computers. It is recognized that there can be "unconscious" and "conscious" perceptions and that both can be valid inputs into the system. The psychological and physiological properties and their relationships are interesting problems for psychology but not central to the theory. (For a further discussion of this point see Irwin, 1971.)

What has been attempted here is the explication of the basic outline of a theoretical account of behavior that views the human individual (as well as the subhuman organism) as a gatherer, processor, and user of information rather than as a simple reactor to external carrots, whips, and the stimuli associated with them. We have been rather explicit about the nature of the information processed and have hypothesized a formal system that utilizes the several items of information in the process of generating behavior.

This account seems not to be a "theory" in the sense that that term has been used by psychologists, but psychologists in general are not accustomed to axiomatic theories. One could not "disprove" the maximization axiom. Certainly, specific pieces can be tidied up if one wishes to make certain assumptions. For example, if one assumes a fairly direct relationship between probability of observed behavior and our variable p under certain conditions, then it is possible to agonize over the details of changes in p for various experimental manipulations. The fact that it might be important to study such changes is highlighted by the theory. Thus, even though the formulation lacks the feisty properties that challenge the research world to perform an *experimentum crucis*, the heuristic value of the theory as a pointer to truly important areas for research cannot be denied, that is, if one accepts such a theoretical framework.

In a sense, the axiomatic framework has the properties of such historical paradigms as the Ptolemaic and Copernican theories, or the phlogiston and chemical theories (read Conant, 1951, for a fun account of these issues), all of which in essence are not subject to proof or disproof but to pragmatic criteria. The Ptolemaic and phlogiston theories were discarded because they were cumbersome or required ad hoc Band-Aids, and there existed neater, more attractive alternatives, not

necessarily because they were false. They were perspectives for looking at the phenomena of their science that had outlived their usefulness. What seems required to test the usefulness of the approach espoused here is a sympathetic attempt by researchers and theoreticians to utilize the framework to bring order to their theoretical efforts, particularly as these efforts may be attempts to relate disparate portions of psychology.

Attitudes Are Alive and Well and Gainfully Employed in the Sphere of Action

HERBERT C. KELMAN *Harvard University*¹

Gordon Allport began his classic paper on attitudes in the 1935 *Handbook of Social Psychology* with this statement: "The concept of attitude is probably the most distinctive and indispensable concept in contemporary American social psychology." He described the term as

elastic enough to apply either to the dispositions of single, isolated individuals or to broad patterns of culture. Psychologists and sociologists therefore find in it a meeting point for discussion and research. This useful, one might almost say peaceful, concept has been so widely adopted that it has virtually established itself as the keystone in the edifice of American social psychology. In fact several writers . . . define social psychology as the scientific study of attitudes [p. 798].

In the years since publication of Allport's paper, attitudes have, if anything, become even more central in social psychology, largely because they have come to serve as *the* dependent variable par excellence for the major categories of social-psychological research: the sample survey, the questionnaire study, and the laboratory experiment.

In recent years, attitude research has increasingly been subjected to rather far-reaching criticism, often linked with broader critiques of the standard methodologies of social-psychological research. Within sociology, the excessive reliance on survey data has come under increasing attack, most vehemently from the ethnomethodologists. Within

experimental social psychology, there has been a strong movement toward field experimentation, partly motivated by the desire to replace assessment of attitudes in the laboratory with observations of behavior in natural settings.

In my own view of social behavior, attitude is a central concept, and I regard the study of attitudes as a legitimate pursuit in its own right and as a useful component of a multimethod research strategy. For example, studies of the structure and distribution of public attitudes on various social issues or of the determinants of attitude change can greatly contribute to our understanding of societal processes. In particular, attitude assessment combined with other research procedures—such as structural indexes in studies of organizational functioning or behavioral observations in studies of child-rearing practices—can add depth and perspective to the analysis of social phenomena. Too often, however, research has focused on attitudes, not so much because of a primary interest in attitudes per se or in their contribution to complex social processes, but because the assessment of attitudes was the easiest and most convenient way of obtaining data. It is obviously more convenient to distribute questionnaires in our classes, asking students how they would be likely to react in a variety of situations, than to observe their behavior in such situations, or to ask a sample of some population about the functioning of their organization, community, or society, than to make the detailed observations and develop the elaborate indexes needed to study a social system more directly. In many of our laboratory experiments too, after investing a great deal of energy and ingenuity in manipulating the independent variables, we have used attitudes as the cheapest and most painless dependent variable for assessing the effects of our manipulations.

Inappropriate and indiscriminate uses of attitude have raised serious questions about the validity and

usefulness of the concept. Allport, foreseeing such a possible development in his 1935 paper, wrote:

Whether the concept is being overworked to such an extent that it will be discarded along with the past shibboleths of social science remains to be seen. It seems more probable that the ever increasing number of critical and analytical studies will somehow succeed in refining and preserving it [p. 804].

Allport's vote of confidence has, in my view, proven justified. In the intervening years there has been a great deal of theoretical work, leading to considerable refinement and elaboration of the concept of attitude. One immediately thinks of the work of Katz, M. B. Smith, the Sherifs, Hovland, Doob, Peak, Campbell, Rokeach, Heider, Newcomb, Osgood and Tannenbaum, Triandis, Rosenberg, and Fishbein. These and other theorists have provided sophisticated analyses of the concept, have explored its complexities, and have pointed to the types of measurement procedures required to do justice to these complexities. The problem has been that these theoretical refinements have not always been reflected in studies utilizing attitudes. In many studies, attitudes have not only been largely irrelevant to the purposes of the research, but have also been assessed or interpreted in ways that ignore the traditional meaning of the concept and the elaborations it has undergone.

In short, social-psychological research has relied excessively on attitudes, to the neglect of other aspects of the social behavior of individuals and of the functioning of social systems. Attitudes have often been treated as the magical key to the study of social behavior and system functioning. As a result, they have been burdened with descriptive and predictive powers that they do not possess and have been used inappropriately and simplistically. There is clearly a need to broaden the conceptual and methodological repertoire of social-psychological research and to examine carefully the uses and misuses of the attitude concept. I do not feel, however, that these misuses discredit the concept of attitude as such. Attitude remains a viable and potentially powerful concept, as long as we place it firmly in a context of action.

I begin in this article by examining two lines of empirical research that have provided bases for questioning the validity and usefulness of the attitude concept and point out why I do not consider them decisive: studies of the consistency between attitudes and actions, and studies of the effects of counterattitudinal or attitude-discrepant action. I then proceed to present some notes toward a con-

ception of attitudes as imbedded in an action context.

Studies of Attitude-Action Consistency

A series of studies have been designed to explore the relationship between attitudes and overt behavior. Two measures are obtained from each subject: an attitude measure, calling for some kind of verbal response vis-à-vis a particular object; and a behavioral measure, based on observation of the subject's overt response to the object. The prototype of this line of research is LaPiere's (1934) famous study, which found a lack of consistency between the negative responses of a number of hotels and restaurants to a mailed questionnaire, asking them whether they would serve Chinese guests, and the behavior of their personnel toward a Chinese couple that had actually been served at these same establishments a few months earlier. There are cogent reasons for questioning the relevance of the LaPiere study to the issue of attitude-action consistency (see Dillehay, 1973), including the fact that his verbal measure elicited policy statements rather than attitudes in the usual sense of the term. Most of the recent investigators, however, have used more standard procedures for assessing attitudes and have devised specially structured choice situations to obtain an index of overt behavior. The assumption behind this line of research is that if an attitude does indeed represent a predisposition to act toward the attitude object in a particular way, then it ought to be possible to predict responses on the behavioral measure from responses to the attitude questionnaire. However, in his thorough review of studies of the attitude-action relationship, Wicker (1969) concluded that "taken as a whole, these studies suggest that it is considerably more likely that attitudes will be unrelated or only slightly related to overt behaviors than that attitudes will be closely related to actions [p. 65]." He went on to say that his review "provides little evidence to support the postulated existence of stable, underlying attitudes within the individual which influence both his verbal expressions and his actions [p. 75]," although he did not reject the concept of attitude as such.

This series of studies have been very useful in pointing to the complexities of attitudes and in challenging the naive assumption that attitudes are direct indicators of overt responses and that assessment of attitudes can thus serve as a cheap substitute for more elaborate studies of social be-

havior. Of particular value are those studies that go beyond the question of whether attitudes and actions are consistent, and explore some of the conditions that make for greater or lesser consistency. For several reasons, however, the low correlations between attitude and action found by many of the studies in this genre, though pointing to the limitations of the attitude concept, do not demonstrate its invalidity.

1. First, we must look at these studies in the perspective of other empirical information—based mostly on survey research—that does show systematic relationships between attitudes and actions. In the area of intergroup relations, for example, studies have shown attitudes toward particular racial, religious, or national groups to be systematically related to personal associations or to voting behavior. Studies of political action have often shown consistent differences in attitude between participants and nonparticipants in certain protest movements or political organizations. In many of these studies, it is impossible to establish the causal direction of the relationship. A notable exception is a recent study by Brannon et al. (1973). Attitudes toward open housing were elicited in the course of a larger survey and actions were assessed by way of a field experiment carried out three months later, in which the original survey respondents served as subjects. The study found substantial relationships between survey responses and willingness to sign and publicize petitions favoring or opposing open housing.

The finding of greater *consistency* between attitudes and actions in studies based on survey designs than in those reviewed by Wicker (1969), which mostly involve experimental designs, brings to mind Hovland's (1959) discussion of the greater *stability* of attitudes in the face of persuasive communications shown in survey as compared to experimental studies. The effect of attitudes on actions may be exaggerated in survey-type studies, which generally use correlational designs, because of the ambiguity of the causal relationships involved. On the other hand, survey studies typically focus on actions more or less freely chosen by the subject—how he votes, with whom he associates, what groups he joins—whereas experimental studies present the subject with a structured situation in which he has to take some kind of action. It may be that in such a structured context situational constraints play a larger role and thus tend to attenuate the effect of attitudinal differences. Attitude-action

consistency may be further attenuated in some experimental studies by the use of attitudes that are less well formed and by their assessment in a classroom context (Brannon et al., 1973). In any event, the sometimes conflicting results of survey and experimental studies must be taken into account in any effort to determine the validity of the attitude concept.

2. Attitude theory does not propose that a person's underlying attitude to an object is the sole determinant of his behavior when interacting with that object. This is even more obvious when the attitude refers to a class of objects and the action refers to a specific member of that class. Major determinants of action are the social constraints under which the person operates, including immediate interpersonal demands, as well as normative expectations—conveyed by relevant reference groups—that govern behavior in the situation (Schofield, 1972). Thus, a person may well act in ways inconsistent with his attitude if consistency would require violating a generally accepted norm of interpersonal conduct (e.g., the rules of common courtesy) or deviating obviously and publicly from reference group expectations.

The assessment of attitudes also elicits behavior in a real situation, subject to various social constraints. Such constraints are obvious in LaPiere's (1934) original study, in which the measure of "attitude" was based on a public letter stating hotel or restaurant policy, but they also operate in more traditional attitude assessment situations. Even when responding anonymously, subjects are often inclined to express attitudes that conform to the views normatively prescribed within their milieus. Situational determinants are particularly likely to influence response to attitude measures in the area of race relations, where the attitude questionnaire tends to evoke the tolerance value inculcated by the society—"especially in a college population where verbal adherence to the value of tolerance is likely to be very high [Weitz, 1972, p. 15]." In the action context, on the other hand, the "situational threshold" (Campbell, 1963) for expressing tolerance may be higher. Thus, subjects conforming to the norm of tolerance on the questionnaire may deviate from their expressed attitudes when they find themselves in a concrete interaction situation. This line of analysis suggests that discrepancies between attitude and action are likely to arise in those domains in which people are subject to cross-pressures and internal conflicts,

for example, racial attitudes in white America. As Weitz (1972) pointed out, "Myrdal's 'American dilemma' is largely the societal disjunction between attitudes and behavior, with a tolerant value system conflicting with discriminatory normative patterns [p. 15]."

In sum, inconsistencies, or apparent inconsistencies, between attitudes and behavior often arise because the studies have not taken account of the social constraints that govern the situations in which the action is observed and the attitudes are assessed. When these social constraints are taken into account in interpreting some of the studies showing weak relationships between attitudes and actions (e.g., DeFleur & Westie, 1958; Linn, 1965), the findings fall neatly into place. Studies that have built social constraint deliberately into their designs as an intervening variable (e.g., Schofield, 1972; Warner & DeFleur, 1969) have produced the expected pattern of relationships between attitudes and actions. Situational constraints can also be taken into account in the types of measurement devices used. It is possible not only to use indirect or unobtrusive attitude measures to circumvent normative expectations but also to develop behavioral indexes that are relatively unaffected by situational pressures (Weitz, 1972).

3. Attitude theorists, including Allport as early as 1935, have pointed out that many attitudes and other intrapersonal factors are aroused in any given action situation, which jointly determine the person's behavior. Most studies of the attitude-action relationship have measured general attitudes toward a particular object and related these to behavior in a situation in which the subject interacts with that object or, more typically, with a specific member of that class of objects. To predict *action* toward a *specific* object in a particular *situation*, however, it would be helpful to assess the other attitudinal inputs that, along with general attitudes toward the object, determine behavior.

These include, first of all, attitudes toward the specific object with which the person is interacting. In a situation of interaction with a particular Italian, for example, attitudes toward that Italian or toward the subset of Italians to which he belongs probably account for much more of the variance in behavior than attitudes toward Italy and Italians in general. Second, attitude toward the action itself is an important factor to be considered. Fishbein (1967) has proposed a model in which the person's attitude toward the act—that is, toward performing a particular act in a given situation with

respect to a given object—and his normative beliefs about the act are the two proximate predictors of behavior (or, more precisely, of behavioral intention). Attitude toward the object, according to this model, affects behavior insofar as it affects attitude toward the act and normative beliefs. In one experimental test of this model, Ajzen and Fishbein (1970) have found attitudes toward the act to be systematically related to behavior in a Prisoner's Dilemma game.² A third type of attitude that must be considered is attitude toward the situation. Rokeach (1969) has argued that prediction of behavior toward an object requires a systematic analysis of the interaction between attitudes toward the object and attitudes toward the situation in which the object is encountered.

Assessment of these diverse attitudes may well improve our ability to predict action. There is some evidence that predictive power is indeed enhanced when a variety of attitudes and related intrapersonal factors are taken into account (Wicker, 1971).

A further complication arises from the fact that the particular attitude object in which the investigator is interested is not the only object toward which the subject is reacting in the situation, and it may not be the most important one. The investigator may define the experimental situation as one of interracial contact, for example, and thus expect behavior to be highly correlated with racial attitudes. The subject, however, may define the situation primarily in terms of its authority structure or its task requirements, and his behavior may be most influenced by his attitude toward authority or toward the task, rather than his attitude toward his laboratory partner. We may, therefore, find only weak or even inverse relationships between racial attitudes and behavior in this situation. The low correlations between attitude and action found in many studies may thus be due to the investigators' failure to explore the entire range of attitudes that operate in the situation and to determine which of these are most relevant to the behavior observed.

² Attitude toward the object—that is, the other player—showed much weaker relationships to behavior, but this is completely understandable because the subjects had no prior attitudes toward each other and their overall relationship was irrelevant to the experimental instructions and manipulations. It should also be noted that attitude toward the act, as conceived and measured by Fishbein, already reflects attitude toward the object along with other factors.

The joint operation of this congeries of attitudinal factors means that attitude toward a particular object does not have as much predictive power as some optimists have hoped it would have. It is one more reason for concluding, however, that the low correlations obtained in many studies of attitude-action consistency do not necessarily invalidate the attitude concept as such. They merely confirm the view that the use of attitude in the prediction of action requires a refined and detailed assessment of attitudes, as well as a thorough analysis of the action situation to which we hope to predict, including the social constraints that govern that situation and the variety of attitudes that are aroused within it.

Studies of the Effects of Counterattitudinal Action

The second line of empirical research that has raised questions about the attitude concept is research on the effects of counterattitudinal action. The theory of cognitive dissonance (Brehm & Cohen, 1962; Festinger, 1957) and Bem's (1967) reformulation of dissonance phenomena in terms of processes of self-perception have generated many experiments demonstrating attitude changes following upon discrepant action. These formulations have been very useful in calling our attention to a number of intriguing phenomena and providing handles for interpreting certain behavioral anomalies. Above all, they have stimulated thinking and research on a central issue in the study of social behavior: the emergence of attitudes out of an action context. They can be used, however, to support a rather narrow view of the action-attitude link, underestimating the dynamic quality of attitudes.

Within the dissonance and particularly within the self-perception framework, attitudes can readily be viewed as epiphenomenal—as cognitive adjustments the person makes after he finds himself acting in a certain way, designed to restore cognitive consistency or to label his action appropriately to himself and to others. Attitudes, in this view, do not perform a directive and dynamic function in behavior but are basically a form of self-indulgence. The experiments on counterattitudinal action, derived from these two traditions, could be used to challenge the concept of attitude as a predisposition to behavior on the grounds that observed relationships between attitudes and actions reflect the effects of action on attitude rather than the

reverse. For several reasons, however, I feel that these studies do not warrant the conclusion that attitudes are epiphenomenal and lack explanatory power.

1. The studies of counterattitudinal action must be seen in the perspective of other empirical information—developed outside of a dissonance or self-perception framework—about attitude changes following upon action. A variety of studies of role playing (cf. Elms & Janis, 1965; Janis & Gilmore, 1965; Janis & King, 1954; Kelman, 1953) have shown some of the conditions under which advocacy of a counterattitudinal position in a role-playing context leads to attitude changes. Studies of the effects of role enactment in real life, such as the well-known study by Lieberman (1956), have demonstrated systematic changes in attitude as the person changed his role. Studies of intergroup contact, such as the Deutsch and Collins (1951) study of interracial housing projects, have shown that under the proper circumstances, such personal contacts may lead to attitude change. There is also some indirect evidence that the introduction of a new policy as a *fait accompli* may produce not only behavioral acceptance, but in its wake also attitude change (cf. Allport, 1954; Saenger, 1953).

In all of these studies, attitude change following upon action can be understood in terms of the usual processes by which, according to the various attitude theories, attitudes are formed and modified. That is, the nature and the consequences of the action bring to the fore challenging insights, role expectations, social supports, or direct experiences, which are the stuff out of which attitudes emerge. The data could, of course, be reinterpreted in dissonance or attribution terms, but they do not need to be explained in these terms. There is nothing anomalous about them from the point of view of attitude theory. Certainly they do not suggest a view of attitudes as epiphenomena and as mere cognitive adjustments. Thus, the recent experiments on counterattitudinal action represent only a limited range of the situations in which actions produce attitude change, and hence they provide an insufficient basis for generalizations about the nature of attitudes.

2. Dissonance theory is concerned with the person's reactions after he has engaged in a discrepant action. His reasons for engaging in the action are of interest to the theory only insofar as they affect the degree of justification for the action (as perceived by the actor), and hence the amount of dissonance aroused. The theory and the experi-

ments flowing from it have not been concerned with the specific motives, expectations, and situational forces—in a qualitative sense—that lead to the action. From a functional point of view, which my colleagues and I have taken in a series of experiments on counterattitudinal behavior (Kelman, Baron, Sheposh, & Lubalin, in press), the initial reasons for engaging in the action determine the kind of dilemma the person confronts and the way he proceeds to resolve it. Systematic attention to these reasons should thus allow us to make more refined predictions of the probability and nature of attitude change, as well as of other reactions, following upon discrepant action.

Most importantly, for the present purposes, an analysis of the person's reasons for engaging in the action may reveal that there were indeed some meaningful relationships between his initial attitudes and the action he has taken. It may well be that the impression, conveyed by the literature on counterattitudinal behavior, of a disjuncture between attitude and action—of attitude as merely a post hoc adjustment to action—derives from the design of studies in this genre, which deliberately separates the induced action from the motives behind it. Kelley's (1967) analysis of the way in which the typical dissonance experiment creates the illusion of freedom in the subject is very helpful in showing how this separation occurs. In view of their special character, these studies cannot provide a sufficient basis for concluding that attitudes do not determine action but merely follow upon it.

3. The internal logic of research on counterattitudinal behavior forces the view that attitudes, though cognitively adjustable, are indeed "real" and play a directive role in behavior. Most dissonance theorists would, I believe, concur with this conclusion. According to dissonance theory, a person changes his attitude because he has behaved in a way that did not "follow from" his original attitude. There is thus the presumption that the person normally expects his behavior to follow from his attitudes and perhaps even feels that it ought to follow from his attitudes (although dissonance theory does not spell out this part of the phenomenology), and that much of the time a person's behavior in fact does follow from his attitudes. Furthermore, attitude change reduces dissonance because it provides the person with an attitude from which his earlier behavior follows retroactively. The new attitude can fulfill that function only insofar as it is "real," and, if it is real, it should have a directive effect on subsequent be-

havior. That is, unless the counterattitudinal action was of the one-shot variety with no implications for the future (which, of course, it often is in dissonance experiments), the new attitude should, at least for some time to come, predispose the person to behavior that follows from it. If attitudes appear ephemeral in many dissonance experiments, it may be because the objects to which they refer and the behavior to which they are linked are ephemeral. However, when applied to real-life situations, dissonance theory does assume that attitudes are real and have implications for behavior.

This reasoning does not apply as clearly to a Bemian type of attribution analysis because, in Bem's view, attitudes in the sense of internal states are by definition not "real." Insofar as any attitudelike phenomenon can be real for a radical behaviorist, however, the attitude statements following counterattitudinal action are real in Bem's scheme; they certainly must be viewed as directive with respect to subsequent behavior. In Bem's analysis, these statements reflect self-perceptions, which he regards as functionally similar to the perceptions of others. Just as our perceptions of others clearly influence our behavior, so should our self-perceptions, according to the internal logic of Bem's scheme. If I see myself as liking brown bread, to use Bem's favorite example, I am more likely to buy brown bread, to serve it to my friends, and so on. In other words, when a person makes an attitude statement following upon counterattitudinal action, he is not merely labeling his behavior for the benefit of others or for his own amusement; his self-descriptions constitute relatively stable determinants of his subsequent behavior.

In short, I have argued that the logic of the research on counterattitudinal action requires a view of attitude as something more than an epiphenomenon and a cognitive adjustment, even though it does follow upon behavior. If one accepts the dissonance or attribution interpretations of the findings, one cannot at the same time cite these findings as evidence of the bankruptcy of the attitude concept.

Toward a Conception of Attitude as an Integral Part of Action

I have come to the defense of the attitude concept, not only because I have a vested interest in it, but because I consider some such concept as attitude to be essential for social-psychological analysis.

It is very difficult to imagine a social psychology without a construct designed to capture the conceptions of social objects and events that people bring to their interactions with each other and with their social institutions and that they share, to varying degrees, with other members of their diverse groups, organizations, and communities. To reject the construct on the basis of the current evidence would be to abandon prematurely a major conceptual tool. Nor does it seem fruitful to argue whether or not attitudes exist; the question is whether they can be conceptualized in ways that yield useful analyses and insightful conclusions about social behavior.

The priority need at this point is for more refined conceptualizations of attitudes, particularly—in view of the challenges presented by the two lines of research discussed above—of their linkage to action. In the remainder of this article I offer some notes toward such a conceptualization. Much of what I have to say has been stimulated by the research on attitude-discrepant behavior—both the work of others, carried out mostly in a dissonance or attribution framework, and the work that my colleagues and I have done within a functional framework—and attempts to put that work into a broader context in which the dynamic connections between attitude and action become more apparent.

Attitude, in my view, and in the view of most attitude theorists, is not an index of action, but a determinant, component, and consequent of it. Furthermore, it is not an entity that can be separated—functionally or temporally—from the flow of action, but is an integral part of action. Attitude and action are linked in a continuing reciprocal process, each generating the other in an endless chain. Action is the ground on which attitudes are formed, tested, modified, and abandoned.

From its very origin, an attitude is embedded in an action situation. A person's attitudes toward a particular object are formed in the course of his interaction with that object, or his interaction with other persons or with communication media transmitting information about the object. These interactions may yield information (a) about the object itself, obtained through observation, hearsay, or some combination of these; (b) about the attitudes of others and the prevailing group norms vis-à-vis the object; or (c) about the person's own relationship to the object, particularly in the form of feedback from his own actions toward it. The way in which the information is processed is a function of the motivational and cognitive contexts in which

the interaction occurs. That is, the attitude the person forms is grounded in the particular functional significance that the situation has for him—the goals he is pursuing, the values he is hoping to maximize, the coping processes in which he is engaged (cf. Katz, 1960; Smith, Bruner, & White, 1956). Similarly, the attitude he forms is linked to the particular cognitive framework within which the interaction occurs—the values defining the situation; the issues under consideration, the other objects involved. The motivational and cognitive contexts in which the attitude is formed determine the nature of the resulting attitude—that is, the motivational basis of the attitude and the attitude system of which it becomes a part—and hence the conditions under which the person is likely to act on this attitude in one or another way, as well as the conditions under which the attitude is likely to change.

This dynamic view of the functioning of attitudes implies that attitude formation and change is a continually ongoing process. Attitudes develop out of the person's interaction with an object in a particular motivational and cognitive context. As he continues to interact with the object (directly or indirectly), the attitudes are tested, exposed to new information, sometimes filled out and shored up, and sometimes changed. In principle, attitudes should be developing and changing whenever a person is exposed to new experiences and information. In practice, changes are usually quite slow and gradual, because attitudes, once established, help to shape the experiences the person has with the attitude object. They affect the kind of information to which the person will be exposed, the way in which he will organize that information, and often (as in interpersonal attitudes) the way in which the attitude object itself will behave. Thus, an attitude by its very functioning (quite apart from any special motivations to maintain that attitude) tends to create the conditions for its own confirmation and to minimize the opportunities for its disconfirmation.

As a person interacts with an object toward which he has established an attitude, he is subject, then, to two competing sets of forces. On the one hand, the new information to which he is exposed produces forces toward change. On the other hand, the existing attitude creates forces toward stability—not only in the form of motivated resistances to change (stemming from the functional significance the attitude has for the person), but also and primarily in the form of confirmatory

experiences inherent in the day-to-day functioning of attitudes. Which of these two sets of forces will prevail on any given occasion—or what balance between them is achieved—depends on the nature of the existing attitude, of the new information to which the person is exposed, and of the situation in which the interaction occurs. In general, however, it can be said that both stability and change are parts of the essential nature of attitudes.

Attitude change processes are most likely to be set into motion if the person is sharply confronted with a discrepancy between his attitude and some item of new information. The discrepant information must be sufficiently strong and challenging to overcome the competing forces toward stability, and even then, as we well know, there are many ways of neutralizing the discrepancy short of attitude change. Three major types of discrepancy conducive to attitude change can be identified, corresponding to the three types of information about an attitude object mentioned above: (a) discrepancy between the attitude and information about reality (e.g., about the characteristics of the object or the implications of the policy to which the attitude refers); (b) discrepancy between the attitude and the attitudes of significant others; and (c) discrepancy between the attitude and one's own actions—which is the focus of the present analysis.

Discrepant Action and Attitude Change

Perhaps the most significant contribution of dissonance theory is that it has focused our attention on *discrepant action*, which constitutes a major arena for attitude change. Discrepant action, as used here, refers to any action toward an object that is out of keeping, from the actor's own point of view, with his attitude toward that object. We usually apply the term to actions that in some way "fall short" of the attitude—that is, fail to live up to the level of commitment that the attitude represents. Such failure may occur because actions in line with the attitude appear too costly and difficult, because they are inhibited by situational pressures, because their anticipated consequences are too negative, or because competing motives impel the person to follow a different course. Discrepant actions, however, may also take the form of actions that "exceed" the person's attitude—that are at a higher level of commitment than that implied by his attitude. Situational pressures or social facilitation may induce him to act in ways that are more

TABLE 1

The Conduciveness of Action to Attitude Change

Components of action	Processes generated by action	
	Motivational	Informational
Context of the action	Meeting task and situational demands	Coding information about object and social expectations
Contemplation of the action	Justification of action	Definition of object and of self vis-à-vis object
Consequences of the action	Anticipation and fulfillment of new role requirements	Integration of new experiences

generous, more courageous, or more tolerant than his attitude requires.

Commitment to a discrepant action may create the conditions for reassessment and revision of related attitudes and thus set a process of attitude change into motion. Attitude change, in the present view, is not a reaction to the discrepancy as such, aimed at removing the inconsistency between action and attitude, but rather an outcome of various motivational and informational processes that are generated by the action. Table 1 presents a classification of six such processes, all of which are likely to come into play, at some level of intensity, in any action situation. Attitude change may be mediated—under the appropriate circumstances—by any one of these processes or any combination of them.

The columns of the table refer to motivational and informational processes, respectively. The rows refer to three components of the action, each of which generates both motivational and informational processes that are potentially conducive to attitude change. The first row refers to the processes generated by the context of the action—the situation in which the person decides to act and carries out the action. The second row refers to processes generated by the contemplation of the action—the person's backward look at the action he has taken and its implications. The third row refers to processes generated by the consequences of the action—the actual and anticipated events that the action brings in its wake. For any given unit of action, the three rows correspond to a focus on the present, on the past, and on the future, respectively. Proceeding row by row, I shall describe the motivational and informational processes that may come into play.

1. *Context of the action.* Let us assume, for illustrative purposes, that a student is urged by his friends to participate in preparing and signing a statement to the university administration protest-

ing against classified research—an action that does not flow spontaneously from his current attitudes. To the extent that he is motivated to meet the demands of this particular situation, this request sets a decision-making process into motion. He assesses the options available to him and their respective consequences; he decides whether or not to engage in the action; and, if his decision is positive, he determines the nature and extent of his participation and previews the content of what he will be doing. In the course of the decision making, he is likely to think through the issues raised by the action, to consider appropriate information, and to review relevant arguments. These efforts, in turn, may involve him in an active process of reevaluating his position—of reconsidering the implications of his original attitudes for his own values and for his relationship to important reference groups. The process of reexamination may provide attitudinal support for the action he has been asked to take and may thus lead to attitude change, in the form of internalization or identification or some combination of the two (Kelman, 1961). In other words, attitude change may emerge out of the process of reexamining his attitudes motivated by the situational context of the action.^a

A high degree of choice about the induced action is particularly conducive to attitude change (Kelman, 1962). If the person is undecided as to whether to carry out the action, then the higher his degree of choice, the more likely he is—in the process of arriving at the necessary decision and firming it up—to reexamine his attitudes and to marshal forces in support of the action that he finally selects. He may, of course, decide against taking the induced action, and this negative decision would now have considerable attitudinal support. But if he does take the action, it is likely to be accompanied by attitude change. A high degree of choice may facilitate attitude change even in the absence of indecision, that is, even if the situational forces are so strong that the person is automatically inclined to take the induced action. The fact that he is given the choice may force him

to engage in a process of active self-persuasion to find attitudinal support for the action he has already decided to take.

Once the decision to act has been made, the person's motivation to meet the demands of the task in which he has agreed to participate may bring a further process of reexamination of attitudes into play—depending, of course, on the specific nature of the action. In the example cited before, preparation of the protest statement requires review of the issues and development of appropriate arguments. If the task is to be carried out effectively, the person has to think of supporting arguments and to present them in a convincing way. In the course of engaging in this process, he may become aware of nuances and implications of the issues that he had not considered before and may thus succeed in persuading himself. This is one reason for the potential effectiveness of role playing—even though it may be a mere exercise demanding no commitment from the actor—in producing attitude change, particularly if it requires improvisation (cf. King & Janis, 1956). In reverse role play among conflicting parties, for example, each player, if he is to perform his task successfully, must consider and present the other party's position from the other's point of view. He may thus gain insights into the other's position which were not previously available to him, and modify his own view accordingly.

The motivational processes generated in the action situation are accompanied by informational processes that are similarly conducive to attitude change. In the course of deciding to act and carrying out the action, the person processes various items of information that have attitudinal relevance. Some of this information is conveyed by the context of the action; some is deliberately sought out by the person to enable him to decide and to act; some is generated by the action itself. He may thus acquire data about the characteristics of the object, about the value implications of various policies, about the distribution of opinions on the issue, and about the expectations held by relevant reference groups. These are the kinds of information that typically enter into the formation of attitudes. Exposure to new information of this variety, under the appropriate motivational circumstances, provides the raw material for attitude change.

2. *Contemplation of the action.* Once a person has taken action, the action itself becomes a datum with which he has to contend. Contemplation of

^a In the case described, attitude change actually occurs before the action, that is, in the course of deciding to act. The final action is thus consistent with the person's newly developed attitude, and strictly speaking, therefore, it is not a discrepant action. The total situation, however, can fairly be described as one of discrepant action because the decision to act cannot be sharply separated from the action itself.

what he has done may raise questions about the meaning of the action, about its implications for his self-image, and about the nature of his ongoing relationship to the object of the action. These musings may generate motivational and informational processes conducive to attitude change. This component of action, essentially, is the one on which both dissonance and attribution interpretations focus.

On the motivational side, the fact that a person has taken a particular discrepant action may have negative implications for his self-evaluation. Contemplation of the action may arouse guilt, shame, or some other negative affect, which in turn generates cognitive efforts to justify the action. The precise nature of the reaction depends on the form the action took, the norm that it violated, and the specific motivational system it has thrown out of balance. For example, my colleagues and I (Kelman, Baron, Sheposh, & Lubalin, in press) have distinguished between moral and hedonic dilemmas and proposed that discrepant actions arousing these different dilemmas will generate different resolution processes, often showing different patterns of relationship to the standard dissonance parameters. Efforts to justify the action, for whatever reason, may bring about attitude change, more or less along the lines proposed by dissonance theory. A morally dissonant act, for example, can be justified if the person can convince himself that the object he harmed or the cause he betrayed was not worthy of his loyalty; a hedonically dissonant act can be justified if he can convince himself that the discrepant behavior was really enjoyable and profitable.

Discrepant action is more likely to generate justification processes conducive to attitude change, the greater the individual's personal involvement in the action. Knowledge that he has acted in a certain way toward an object becomes an important datum in the person's self-evaluation and in his evaluation of the object if he regards the action as internally motivated and representative of the self. The sense of personal involvement—and hence the probability of attitude change—should be enhanced if the action is freely chosen, if it requires effort and initiative, and if "it represents a complex of interrelated role behaviors within some social system rather than a specific, isolated act [Kelman, 1962, p. 107]."

Contemplation of the action also provides new information—relevant to the definition of the object and to the person's self-definition—on which

attitude change may be based. The title of the classic collection of children's definitions, *A Hole Is to Dig*, elegantly describes our tendency to define objects in terms of the way in which we characteristically act toward them. The action one takes toward an object tends to become a salient characteristic of that object. It influences subsequent interactions with the object and receptivity to further information about it and thus, eventually, evaluation of the object. For example, if a person has acted in support of a particular policy, he will be inclined to define it, in part, as "a policy that I have supported." This new definition, in turn, may contribute to a new evaluation of it as "a policy that is worthy of my support." Such an outcome can be derived from an analysis of the usual ways in which people process information, without invoking a special need for consistency.

The information provided by contemplation of one's action also has relevance for his self-definition. In line with a Bemian analysis, if a person acts toward an object in a certain way, he will (given the proper stimulus conditions) attribute to himself the corresponding attitude. Beyond that, if the action touches on central concerns, it will contribute to the person's more enduring definition of his self. Thus, repeated friendly association with another person will lead him to define himself as the other's friend; repeated participation in protests and demonstrations will lead him to define himself as an activist and radical. The person's conception of the kind of person he is, in turn, plays a major role in determining his future actions and interactions. Thus, by being integrated into the person's self-definition, the action-generated attitude gains stability and generality.

3. *Consequences of the action.* Most actions, at least outside the laboratory, have consequences beyond the immediate situation. When taking action, therefore, the person prepares himself psychologically for its anticipated consequences. For example, in preparation for the anticipated necessity of explaining and defending his action to others, he may review the issues involved in the action, rehearse the opposing arguments, and reassess his own attitudes toward the object of the action. Out of this process, attitude change may emerge, particularly since the person is motivated to find arguments supportive of the action he has taken. If he not only knows these arguments but actually believes them, his ability to offer a comfortable and convincing defense of his action is further enhanced.

The motivation to bring one's attitude into line with his action is especially strong if the action commits the person to continuing association or public identification with the object and hence, at least implicitly, to future action in support of it. Many simple acts, such as buying a product, making a pledge, or allowing one's name to be placed on a mailing list, have this consequence. Of special interest, however, are those actions that involve commitment to a new role, such as the act of joining an organization, moving into a new neighborhood, starting a new job, or entering a training program. These actions represent long-term commitments, which would be costly to break; they involve the person in an extensive set of role relationships; and they often become salient features of his public identity. Under these circumstances, the development and strengthening of appropriate attitudes in preparation for the new role becomes particularly crucial. The person is open to and actively searches for new information that lends attitudinal support to his action and thus makes his anticipated role performance more effective, more comfortable, and more rewarding. These preparatory processes are likely to facilitate attitude change in the direction of the action taken and of the future actions anticipated (cf. Kelman, 1962).

Not only the anticipated but also the actual consequences of action generate motivations for attitude change, particularly when the action takes the form of commitment to a new role. The requirements of the new role produce strong forces toward reexamining one's attitudes and making them congruent with the expected role performance. Thus, for example, if the worker in Lieberman's (1956) study who becomes a foreman is to be effective in making the choices and taking the actions required by his new status, he must develop the appropriate attitudes. If he is to be able to defend the position of management, he must know it and is likely to adopt it. Moreover, the tendency of others to cast him into the role of spokesman for management and expect him to take management-oriented positions has the self-fulfilling effect of binding him into the role so that he becomes what others expect him to be. To take another example, the white housewife in the Deutsch and Collins (1951) study who has moved into an interracial housing project is motivated to reexamine her racial attitudes because she is now involved in regular interaction with black neighbors, because she is called on to defend her decision to move into the

project, and because she is identified by others as a resident in interracial housing. In short, enactment of the new role in which the person finds himself as a consequence of action sets into motion various forces conducive to attitude change, not the least of which are the expectations conveyed by others and their tendency to attribute certain attitudes to him and to treat him accordingly.

On the informational side, a frequent consequence of action is to provide the person with new experiences, which may expose him to new information. The experiences may be in the form of more extensive contact with the attitude object itself. Thus, the worker-turned-foreman in Lieberman's study has increased contact with management, which, given his openness to new information supportive of his new role, is quite likely to provide him with raw material for attitude change in the direction of management. The white housewife in the Deutsch and Collins study has new opportunities to interact with her black counterparts in daily activities and around common concerns, which, depending on what happens in the course of the interactions and on her motivation to receive favorable information, may produce favorable attitudes. The literature on intergroup contact suggests that contact at least provides the potential for new experiences conducive to attitude change. Favorable change is most likely if the contact involves equal-status interactions and if it is sanctioned by legitimate authorities—conditions that were met in the Deutsch and Collins study.

Action may also provide the person with new social experiences that indirectly yield new information about the object. His action in support of a particular group or policy, for example, may elicit praise from others, or at least fail to elicit the disapproval he had anticipated; or he may discover unexpected agreement, at least within his relevant reference groups, with the stand he has taken. These new items of information about group consensus and about the social acceptability of his action may contribute to attitude change via the process of identification. In short, as the person integrates new experiences consequent to the action, whether these involve direct contact with the object or contact with social norms about it, forces toward attitude change may well be set into motion.

To sum up, Table 1 presents a preliminary mapping of the processes generated by discrepant action. I have tried to analyze attitude change following upon action in terms of the variety of conditions, motivational and informational, that

govern the formation and functioning of attitudes. The analysis is intended to show that the action-attitude sequence can be understood if we conceive of attitude as an integral part of action. The need now is for more precise propositions about the determinants of attitude change within each of the six cells of Table 1. Such propositions can be derived from a variety of theoretical sources and integrated into a functional analysis. Each cell of the table, in fact, suggests a social-psychological theory that is particularly relevant as a source of propositions. I have in mind the theories of decisional conflict and information processing for the cells in the first row, dissonance and attribution theories for the cells in the second row, and role theory and contact theory for those in the third row.

Action as a Step in the Attitude Change Process

The discussion in the preceding section proceeded from the assumption that a discrepant action has occurred, and then explored the various ways in which this event may lead to attitude change. It is often true, however, that action—even discrepant action—does not merely precipitate attitude change, but is itself an integral part of an ongoing attitude change process.

When we examine a person's reasons for taking an apparently discrepant action, we may find that the action is not completely out of keeping with his attitudes. Though he may be responding to situational demands, to interpersonal pressures, to social facilitation, or to other extraneous influences, his response need not be entirely unwilling. The action may reflect an incipient attitude change, a movement toward a new attitude that has not yet been crystallized and to which he has not fully committed himself. Extraneous forces may thus precipitate an action for which the person was already partly prepared. The action in turn contributes to attitude change, in the sense that it provides an occasion for the person to sharpen the new attitude and commit himself to it. In short, attitude change in relation to discrepant action is not always an entirely *reactive* process, but may well be an *active* process in which action plays a catalytic role.

This process can be understood quite readily if we assume, as a number of attitude theorists do, that an attitude indicates a range, rather than just a point on a scale. Specifically, I propose that any

given attitude represents a *range of commitment* to the attitude object. This notion clearly overlaps with the concept of latitude of acceptance (Sherif & Hovland, 1961), except that it refers to action potential—to the kinds of action the person is prepared to take—rather than to judgment. Within a person's range of commitment, one can identify a point representing his modal level of commitment (which is presumably the point to which a person's position on an attitude scale would correspond, if it were possible to devise situation-free attitude measures). A person's behavior vis-à-vis the attitude object fluctuates around that modal point. In some situations he may display a level of commitment closer to the upper end of his range; in others, a level closer to the lower end.

The notion of a range of commitment suggests not only fluctuations around a modal level, but also a readiness to shift one's modal level to another position within the range, given the proper circumstances. The degree of readiness for such a shift, the direction it would take, and the circumstances that might precipitate it depend on a variety of qualitative factors. The possibility of such a shift to a higher or lower level within the person's range may be entirely latent, or it may be actively entertained or even desired by the person. For example, a person may be willing or even eager to become more actively involved in an organization or a profession—to give more of his time to it or to take a leadership role—but the opportunities to do so have not presented themselves or other competing forces have kept him at his present level. Conversely, a person may feel ambivalent toward an organization or a social group to which he belongs, and be willing or even eager to withdraw from it, but the opportunity to do so gracefully in the face of competing considerations has not arisen.

Within this framework, one can see how an action can simultaneously flow from an attitude and mediate changes in that attitude. Table 2 sketches out some classes of situations in which this kind of process may occur. The first row describes the general characteristics of these situations: (a) A person (P) finds himself in a situation calling for action at a level higher or lower than his modal level of commitment, but still within his range. (b) For one or another reason, he decides to take this action, which thus involves him at least temporarily at a level of commitment higher or lower than his usual level. (c) Having taken the action, he becomes subject to the various action-generated forces conducive to attitude

TABLE 2

Action as a Step in an Ongoing Process of Attitude Change

Case	Preacton attitude	Nature of action	Impact of action
Generic case	Action called for is higher (lower) than P's modal level of commitment, but within his range of commitment.	P responds to opportunities, challenges, or internal forces to take action corresponding to a level of commitment higher (lower) than his modal level.	Action generates processes conducive to attitude change in form of higher (lower) modal level, and heightened (lowered) and/or narrowed (widened) range of commitment.
Case 1: Opportunity	P is prepared (e.g., through anticipatory socialization) for level of commitment higher (lower) than current modal level.	P utilizes opportunity to adopt previously anticipated role corresponding to a higher (lower) level of action commitment.	Role enactment generates experiences, task requirements, and social expectations that lead to higher (lower) level of commitment.
Case 2a: Social challenge	Level of commitment higher (lower) than current modal level is latent in P's attitude, but unexpressed because of cross-pressures or other competing forces.	P yields to social pressure to take action in line with expectations of one reference group.	Action generates motivational and informational processes that reinforce and facilitate movement to higher (lower) level of commitment.
Case 2b: Cognitive challenge	Level of commitment higher (lower) than current modal level is latent in P's attitude, but unexpressed because of failure to draw implications of own values.	P confronts implications of own values to take action in line with his revised self-expectations.	
Case 3: Self-mobilization	P wants to move to level of commitment higher (lower) than current level, but is kept back by cross-pressures or other competing forces.	P takes action as part of deliberate effort to mobilize internal and external support for movement to a new level.	Action places P in new psychological and social situation that requires and supports shift to higher (lower) level of commitment, and prevents backsliding.

Note. P = person.

change, which were discussed earlier; as a result he may manifest change by raising or lowering his modal level and his entire range, as well as by narrowing or widening the range. This generic case merely describes what happens, but does not explain why the person decided to take action discrepant from his modal level in the first place. For this, let me turn to the more specific cases.

Case 1 can be exemplified by the workers in Lieberman's study. The fact that a given worker was asked to be a foreman or a steward was probably not a mere coincidence. The chances are that he was available for this level of commitment to management or the union, that he had been moving in that direction for some time, that he had been building relevant attitudes in preparation for it—in short, that he had been undergoing a process of anticipatory socialization. The invitation to become a foreman or a steward thus represented an opportunity for him to adopt a role for which he was already prepared. It must be noted that al-

though he was clearly ready for attitude change, his attitudes were not yet at the level of a functioning foreman or steward. It took the action commitment and all the forces that it generated to bring a new attitude—at a higher level of commitment—into sharp focus, to reorganize it, and to stabilize it.

Another example of Case 1 would be the person who joins a social movement. The point of joining represents a clearly identifiable, highly committing action step. The decision to take the leap and to define himself as a member is a critical one, and major changes in attitude are likely to follow from it. Yet, the action was obviously not unrelated to these new attitudes. The changes were no doubt already taking place, slowly, perhaps imperceptibly, prior to the action. The act of joining the movement helped to speed up the rate of change and to sharpen and crystallize the new attitudes. Similar considerations apply when a person decides to leave a movement. Typically, his commitment to the

movement has been becoming weaker for some time, but he has not quite reached the point of changing his modal position. When a turning-point in his own life or in the life of the movement finally precipitates his decision to quit—for which he had been gradually preparing himself—his attitudes change sharply and rapidly.

Case 2a might be exemplified by the student from a fairly conservative background whose political views and commitments have been moving in a new direction. He has settled into a generally liberal position, marked by support for various causes but not a high level of personal involvement in them. The possibility of a deeper commitment to some of these causes is within his attitudinal range, but he is not quite ready for it because he is not willing to break entirely with his family and home community, or because he is not prepared to pay the price of higher commitment, or because he has not fully sorted out his ideas on the matter. As often happens, this individual may find himself in a situation in which social facilitation or social pressure from his current associates induces him to participate in political action that exceeds his modal level of commitment, and this action in turn generates further attitude change. Although situational forces played a major role in inducing the action, he was at least partly ready for it. In fact, he may have had a latent interest in trying out this higher level of commitment but needed the extra push that social pressure provided. Other examples of Case 2a are the conscience-stricken anti-integrationist who welcomes external pressures, in the form of laws or *faits accomplis*, that constrain him to go along with integration (Allport, 1954); and the "latent liberal" in the South who is racially prejudiced for reasons of conformity but quite ready to change once the social norms point in the direction of greater tolerance (Pettigrew, 1961).

Case 2b is structurally similar to 2a, except that movement to a different level of commitment is inhibited, not by the existence of cross-pressures, but by the person's failure to make certain cognitive connections. For example, a young man may have serious moral compunctions about war and thus be a latent conscientious objector. He may never have considered taking this position, however, because he was unaware of the existence of this social category and because it never occurred to him that response to the draft law was within a person's domain of moral choice. Once confronted with the possibility of taking this action, he may

acquire a new perspective on the problem and recognize himself as someone who has been a conscientious objector all along without ever knowing it. This example and others of this type usually represent some mixture of social facilitation and cognitive challenge.

Case 3 represents the most interesting illustration of action as a step in an ongoing process of attitude change. It refers to a person who really wants—with at least some degree of consciousness—to move to a different level of commitment, but who, for various reasons, is not quite ready to do so. Examples would be the political activist who wants to engage in more militant action but is reluctant to pay the price it would entail; the religious seeker who would like to make a complete commitment but lacks the faith to take the final leap; or the graduate student who is profoundly interested in the field of his choice but hesitates to make a lifelong commitment to it. In such a situation, the person may deliberately take an action that is beyond his current level of commitment. The political activist may decide to engage in an act of civil disobedience; the religious seeker may decide to spend a summer with the sect he is attracted to; the graduate student may accept a research assistantship in an area he knows he will find engrossing. These actions do not represent a total commitment, but they do represent identifiable steps in that direction.

To some extent, the person may take this step in order to test his level of commitment, on the assumption that true commitment implies a readiness to take actions of this kind. The action thus provides him an opportunity to demonstrate his commitment to himself (as well as to others)—or perhaps to determine, once and for all, that he really lacks the commitment. Even more intriguing is the possibility that such actions are taken to bring about a deeper level of commitment. The person is at least vaguely aware that by taking this action he places himself in a situation in which he will gradually be propelled into increasing commitment. The action creates some irreversible consequences. For example, by committing an act of civil disobedience, the political activist risks jail, which in turn may greatly limit his future opportunities. Furthermore, the person's action creates expectations in others—both those who share the action and those who witness it—who will then treat him as one who is fully committed to the cause. By setting up these expectations in others,

he makes it more difficult for himself to withdraw, for both practical and psychological reasons. In short, by taking the action, he is not only testing and mobilizing his own commitment but also mobilizing external forces to support a strengthened commitment and to prevent him from backsliding. The array of forces generated by the action thus helps him to shift to a new level of commitment and to jell an attitude that was not yet fully formed prior to the action.

In Case 3, as in the other cases summarized in Table 2, action creates commitment and generates attitude change. Yet, at the same time, the person's readiness for such change is partly responsible for his original decision to take the action. Case 3 is of particular interest since it represents a person's deliberate attempt to use a partially discrepant action as a vehicle for attitude change. It demonstrates the potential interactions, both between deliberate choice and external constraints, and between action and attitude change. It shows most clearly the engagement of attitude and action in a continuing, reciprocal, circular process. Not only is attitude an integral part of action, but action is an integral part of the development, testing, and crystallization of attitudes.

Instrumental Conditioning of Autonomically Mediated Responses in Human Beings

H. D. KIMMEL *University of South Florida*¹

Forty-five years ago, John Watson (1928) said, "We may earn our bread with the striped muscles but we gain our happiness or lose it with the kind of behavior our unstriped muscles or guts lead us into [p. 349]." The unfolding of events in the years following Watson's statement, however, contrived somehow to obscure its significance, at least until fairly recently. I would like to review some of the circumstances under which American psychology, in the colorful language of Gregory Razran (1972, p. 147), managed to "lose its guts" and, then, I would like to describe some of the recent empirical work on human subjects which has brought about their rediscovery. I will also try to identify some of the theoretical and practical implications of this recent work, since, as Watson implied, its significance is applied as well as basic.

Foundations of the Belief That Autonomically Mediated Responses Are Not Intrumentally Modifiable

1928-1961

In the same year that Watson was emphasizing autonomically mediated behavior, Stefan Miller and Jerzy Konorski (1928) published their landmark article which distinguished for the first time between classical and instrumental conditioning. Miller and Konorski were the first to suggest that responses mediated by the autonomic nervous system cannot be modified instrumentally. A few years later, quite independently, Skinner (1935)

proposed an analogous categorization of the two types of conditioning, but he did not at first exclude autonomic responses from his instrumental category. In fact, one of his hypothetical examples of instrumental conditioning, when the to-be-conditioned response and the unconditioned response are of the same original form, was salivation to light, reinforced by food. Konorski and Miller (1937) responded to Skinner's paper and criticized it vigorously. Referring specifically to his hypothetical example of salivation to light being reinforced instrumentally by food, they said, "Being a glandular reaction, salivation cannot by any means be made a conditioned reaction of the new (i.e., instrumental) type. Skinner's case is not so much imaginary as impossible [p. 271]." In reply to their criticism, Skinner (1937) maintained an open-mindedness regarding autonomic instrumental conditioning. He wrote:

That responses of smooth muscle or glandular tissues may or may not enter into Type R (i.e., instrumental), I am not prepared to assert. I used salivation as a convenient hypothetical instance of simultaneous fused responses of both types, but a skeletal response would have done as well. The child who has been conditioned to cry "real tears" because tears have been followed by positive reinforcement (e.g., candy) apparently makes a glandular conditioned response of Type R, but the matter needs to be checked because an intermediate step may be involved [p. 279].

Skinner's open-mindedness altered somewhat during the one year between his response to Konorski and Miller and the publication of *Behavior of Organisms* (Skinner, 1938). Perhaps because of the inconclusiveness of his experiment with Delabarre, attempting instrumental modification of vasoconstriction, or possibly because both Schlosberg (1937) and Mowrer (1938) adopted Konorski and Miller's position regarding autonomic responses, he wrote the following in *Behavior of Organisms*: "There is little reason to expect conditioning of

¹ This article was originally an invited address to Division 3, presented at the meeting of the American Psychological Association, Montreal, Canada, August 1973.

Requests for reprints should be sent to H. D. Kimmel, Department of Psychology, University of South Florida, Tampa, Florida 33620.

Type R in an autonomic response, since it does not as a rule naturally act upon the environment in any way that will produce a reinforcement, but it may be made to do so through instrumental means [Skinner, 1938, p. 112]." The last phrase indicates some remaining doubt. But by the time *Science and Human Behavior* (1953) appeared, Skinner's position had become almost indistinguishable from that proposed 25 years earlier by Miller and Konorski (1928), namely:

Glands and smooth muscles do not naturally produce the kinds of consequences involved in operant reinforcement, and when we arrange such consequences experimentally, operant conditioning does not take place. We may reinforce a man with food whenever he "turns red", but we cannot in this way condition him to blush "voluntarily". The behavior of blushing, like that of blanching, or secreting tears, saliva, sweat, and so on cannot be brought directly under the control of operant reinforcement. If some technique could be worked out to achieve this result, it would be possible to train a child to control his emotions as readily as he controls the positions of his hands [p. 114].

It would not be fair to Skinner to leave the impression that his open-mindedness was completely gone, however. I say this because of the personal encouragement he gave me just after I had begun to conduct my first experiment on instrumental autonomic conditioning using the galvanic skin response (GSR) of humans. Skinner visited the University of Florida in the early spring of 1959 to give an invited lecture, just after I had begun to run my first subjects. He graciously came to the laboratory to look at the equipment and discuss our research plans. There were no reservations discernible in his urging that we pursue the undertaking. In fact, because of his reservations regarding punishment as a possible means of attaining response suppression, Skinner suggested that we add an experimental condition in which subjects receive reinforcement contingent on nonresponding. It still was, as he had written earlier, "a question for experiment [Skinner, 1937, p. 279]."

Nevertheless, the *public* statements of most major figures in American psychology transformed Miller and Konorski's original exclusion of autonomic responses into unquestioned dogma. As late as 1961, even while at least five different investigators were collecting data and beginning to report preliminary positive findings, Gregory Kimble (1961) wrote:

Although autonomically mediated reactions such as the GSR and vasoconstriction are readily conditioned classically, they seem to be impossible to condition by instrumental methods. The Pavlovians simply state (without documentation available in English) that glandular responses cannot be conditioned instrumentally. Mowrer

(1938) was unsuccessful in an attempt at instrumental conditioning of the GSR, and Skinner (1938) reports that he and Delabarre could not condition vasoconstriction by making reinforcement contingent upon the response. *Thus, for autonomically mediated behavior, the evidence points unequivocally to the conclusion that such responses can be modified by classical, but not instrumental, training methods* [p. 100, italics added].

Evidence that Kimble was aware of at least one positive result at the time he wrote his "unequivocal" statement was given by him in April 1960 in an invited address he gave to the Southeastern Psychological Association. In his talk, entitled "Total Behavior: The Conditioned Eyelid Reflex," Kimble referred to the fact that one of the research papers on the same program (H. D. Kimmel & Hill, 1960) reported successful operant conditioning of the GSR in humans. He indicated that it would take more than a single study to overcome so well established a generalization. To his credit, it must be added that subsequent positive results *did* make Kimble change his position, and in writing: "These data seem to settle the immediate issue. Apparently an autonomic, involuntary, normally elicited (rather than emitted) response can be instrumentally conditioned as single-process theory maintains it should be [Kimble & Garmezy, 1968, p. 319]."

Initial Positive Findings

1957-1961

Toward the end of the 1950s, as mentioned previously, an apparent change in the *Zeitgeist* regarding the possibility of instrumental autonomic conditioning was occurring. At least five different groups of investigators independently were attempting to modify human autonomic responses instrumentally, and all eventually obtained results more or less capable of positive interpretation. Because of their historical priority, I would like to mention them briefly. In the Soviet Union, Lisina (1960) trained human subjects to control digital vasoconstriction and dilation by means of instrumental shock-escape and avoidance, plus visual feedback regarding vasomotor reactions. Her results were first described in English by Razran (1961). Lisina found that her subjects could learn to terminate shock by means of digital vasodilation, overcoming the unconditioned tendency for shock to elicit vasoconstriction. They also could learn to prevent shock entirely by vasodilating instead of vasoconstricting to a light-sound combination presented in advance of shock. None of the subjects showed

these instrumental conditioning effects without real-time feedback of their vasomotor behavior.

At about the same time at the University of Toronto, Mandler (Mandler, Prevan, & Kuhlman, 1962) was attempting to influence the frequency of occurrence of unelicited GSRs, by presenting response-contingent light stimuli. In this study, reinforcement periods were alternated with extinction periods over several days. Six of the nine subjects made significantly more GSRs during reinforcement than during extinction. But, because overall GSR frequency tended to decline throughout the experiment, in both reinforcement and extinction periods, its results were interpreted as negative with respect to the possibility of instrumental autonomic conditioning. Mandler also attempted to train human subjects to discriminate changes in their heart rates (Mandler & Kahn, 1960), but reported that the subjects could do this only when respiration changes occurred.

While these investigations were underway in the Soviet Union and Canada, three other independent autonomic instrumental conditioning projects were in progress concurrently in the United States. Two of these involved heart rate as the autonomic response, with both discriminative reward and Sidman avoidance techniques under study. The discriminative reward work, done by Harwood (1959, 1962), yielded negative results for both increases and decreases in heart rate, but there was some evidence suggesting that very brief decelerations (i.e., changes in the interbeat interval) might be higher in frequency during the presence of S^D than during S^+ . Somewhat more promising results were found by Shearn (1960, 1961) with the Sidman technique, although no significant reduction in the number of shocks received was attained. In Shearn's study, an amplified auditory presentation of the subject's heart beat was delivered to him during the conditioning session, somewhat analogous to Lisina's feedback technique, but not presenting heart rate directly.

The fifth independent investigation of instrumental autonomic conditioning in humans began in my laboratory at the University of Florida in 1958. Our first study employed pleasant and unpleasant odors to reinforce unelicited GSRs (Kimmel & Hill, 1960). In this study the only evidence of an instrumental conditioning effect was that subjects who received response-contingent reinforcement increased sharply in response rate at the beginning of extinction, while subjects who received non-

response-contingent reinforcement decreased in response rate when extinction began. This effect did not depend on which odor was used. We then shifted to a dim white light as reinforcement, with the subject seated in a totally dark room, and instrumental conditioning effects were found during both acquisition and extinction (Fowler & Kimmel, 1962). Postexperimental interviews were used to eliminate subjects who reported anything resembling awareness of a response-reinforcement contingency.

Early Extensions

1962-1966

Following publication of the results of these initial studies, several other laboratories took up the task of investigating instrumental autonomic conditioning in humans. Within the five-year period 1962-1966, the reliability of the initial positive findings with the GSR was firmly established (Greene, 1966; Greene & Nielsen, 1966; Johnson, 1963; Kimmel & Kimmel, 1963; Shapiro, Crider, & Tursky, 1964), and the GSR work was extended to include investigation of instrumental punishment and avoidance (Grings & Carlin, 1966; Kimmel & Baxter, 1964; Kimmel, Sternthal, & Strub, 1966; Senter & Hummel, 1965). All of these studies confirmed the conditionability of the human GSR by instrumental reinforcement. Four additional studies done during this period provided evidence that instrumental modification of the GSR cannot easily be attributed to mediation via an instrumentally conditioned or voluntarily emitted skeletal response (Birk, Crider, Shapiro, & Tursky, 1966; Crider, Shapiro, & Tursky, 1966; Rice, 1966; Van Twyver & Kimmel, 1966). In the Birk et al. (1966) study, a human subject volunteered to be partially curarized, greatly reducing the possibility of skeletal activity, yet showed the effect of instrumental reward training in his GSR.

Extension of the scope and confirmation of the reliability of instrumental heart rate conditioning also was accomplished during the 1962-1966 period. Two studies of heart rate conditioning using an avoidance paradigm were reported, both with positive results. In the first of these avoidance studies, done by Brener (1966), an auditory stimulus which varied directly in frequency with the subject's heart rate was continuously fed back in real time to the subject. Heart rate slowing was the avoidance response. In a second study, Brener (1966) suc-

ceeded in training subjects to avoid shock by means of heart rate speeding. In this study visual feedback was presented, but only at times of criterion responding. Another experiment on instrumental heart rate conditioning, using a punishment paradigm, was reported by Frazier (1966). The subjects in Frazier's study were correctly informed that shock might be delivered whenever a visual stimulus was present and that no shocks would be delivered when the visual stimulus was absent. During the presence of the visual stimulus, declines in heart rate from the rate of the previous minute were punished by shock. Maintenance of the same heart rate prevented the shock, so that this study could also be placed in the avoidance category. No response-correlated feedback was used in Frazier's study, and its results are contaminated by the obvious fact that the administration of shocks during the presence of the visual stimulus may, itself, be sufficient to elevate heart rate or prevent its decline, either directly or via classical conditioning. Heart rate slowing was also obtained by Engel and Hansen (1966), using monetary reward, but without informing the subjects that reward was contingent on heart rate or any other response. No feedback other than the rewards was given. In the Engel and Hansen (1966) study, respiration data did not support a mediation hypothesis. Control of both slowing and speeding of heart rate within the same subjects was obtained by Brener and Hothersall (1966), using auditory feedback correlated with heart rate. The subjects were instructed to try to keep the pitch of the auditory stimulus high when a green discriminative stimulus was on and to try to keep its pitch low when a red stimulus was on. They were not informed that the pitch of the sound was correlated with heart rate. Respiration records indicated that both heart rate and breathing patterns differed in the high and low conditions, but only one of the subjects guessed that respiration might be involved in controlling the sound. None of the subjects guessed that heart rate was involved.

In addition to these GSR and heart rate studies, two experiments on instrumental conditioning of unelicited digital vasoconstriction (Snyder & Noble, 1965, 1966) were also done during the 1962-1966 period. These studies replicated the procedures previously employed with the unelicited GSR and they showed substantially greater increases in response rate during acquisition than had been shown with the GSR and heart rate. Greater resistance

to extinction than that found with the GSR and heart rate was also reported. In the second of these studies (Synder & Noble, 1966), it was reported that the conditioning group did not differ from a yoked control group in respiration rate, heart rate, or electromyogram (EMG), in agreement with the earlier GSR studies and with some, but not all, of the heart rate studies.

Methodological Concerns: Skeletal and Cognitive Mediation

In 1967, I published a summary of most of these findings in the *Psychological Bulletin* (H. D. Kimmel, 1967). By this time there had been 16 published studies of instrumental conditioning of the GSR, 5 of heart rate, and 3 of the vasomotor response, not including the 1938 studies of Mowrer and of Skinner and Delabarre. Evidence showing instrumental autonomic conditioning in humans was reported in all of these 24 experiments. By this time it was clear that the evidence pointed "unequivocally" if not overwhelmingly to the conclusion that autonomically mediated responses of humans are conditionable instrumentally, a conclusion I came to in my *Bulletin* article. But this conclusion did not necessarily mean that the mechanism of instrumental autonomic conditioning was understood or that it was the same as that underlying instrumental modification of skeletal responses, even assuming that the latter mechanism were actually known. The ink was hardly dry on the *Psychological Bulletin* article when Katkin and Murray (1968) argued that instrumental autonomic conditioning in humans could never unequivocally be demonstrated because of our inability to control effectively for skeletal and cognitive mediation. Short of massive curarization, such as now has been done with subhuman subjects (DiCara, 1970), skeletal behavior may always be a possible mediator of changes in autonomic behavior, although the evidence currently available, some of which has already been touched on and some of which will be mentioned below, indicates that "possibility" and "actuality" are not identical.

For example, Rice (1966) found operant GSR conditioning in human subjects who were reinforced for GSRs only when they occurred in the absence of EMG activity. Van Twyver and Kimmel (1966) reported significant differences between conditioned and yoked control groups even when all GSRs that were observed to occur close in time to

respiration irregularities or EMG activity were eliminated from their data. Gavalas (1968) reinforced subjects for making deep respirations, which elicited GSRs, and found that the skeletal respiratory response was learned while the GSR habituated. Commenting on the significance of this "decoupling" methodology, she argued, "If observable skeletal mediators of observable autonomic responses do not produce changes that mimic those seen in operant/autonomic conditioning, it becomes highly unreasonable to suppose that unobservable mediators do [Gavalas-Medici, 1972, p. 108]." And, as has been mentioned previously, Birk, Crider, Shapiro, and Tursky (1966) obtained instrumental GSR conditioning in a partially curarized human subject who was capable of only very limited movement. Several of the studies of instrumental conditioning of heart rate, and one of the studies of vasoconstriction, likewise, appear to have provided adequate evidence that EMG and respiration did not change in concomitance with the conditioned changes in the autonomic response. Even more damaging to the skeletal mediation hypothesis are recent results on instrumental salivary conditioning and on cardiac integration in humans. These studies will be discussed in detail in a subsequent section.

The matter of cognitive mediation is somewhat more complicated, in my opinion, since it is related to the perennial controversy regarding whether any human learning can occur without awareness of contingencies. As Rochelle Gavalas-Medici (1972) recently observed, those who argue for cognitive or other mediation often fail to differentiate between sufficiency and necessity. As she pointed out,

It is necessary—but not sufficient—to show, as Behnaker, Proctor, and Feather (1972) did, that a skeletal mediator (inconspicuous muscle tension) can elicit the autonomic response in question (heart rate). In order to demonstrate the critical role of the mediator, operant reinforcement must be made contingent upon increases in heart rate which are elicited by the increased muscle tension. The careful coupling of the responses and the reinforcer are essential [p. 108].

I would add to this that demonstrations that cognitive strategies may be *sufficient* to elicit autonomic responses do not force the conclusion that such strategies are necessary for changes in autonomic responses to occur. In fact, as I have argued in recent publications (H. D. Kimmel, 1973a, 1973b), consistent eliciting stimuli foster habituation, not maintenance or strengthening of responses, whether they be autonomic or skeletal.

After we had conducted intensive interviews with about 200 subjects in my laboratory, their responses convinced us that we were wasting both our own time and theirs. Ninety-eight percent of the subjects interviewed in our laboratory report no awareness that *anything* they might have done during the conditioning session was correlated with the delivery of the reinforcement. These subjects typically respond with incredulity to our suggestion that something they were doing influenced the reinforcement. This is, of course, reminiscent of the thumb cramps reported by Hefferline's (Hefferline, Kennan, & Harford, 1959) subjects after the extinction phase of his study of instrumental conditioning of EMG activity in the thumb. Hefferline's subjects speculated that the cramps resulted from the tightness of the EMG electrodes. Observations of this type do not *prove* the absence of cognitive mediation, to be sure, but they make the hypothesis more difficult to accept. Similar comments regarding postexperimental interviews have been made by other investigators (e.g., Engel, 1971), who even reported eventually feeling foolish about conducting them.

The data relevant to the possible role played by cognitive factors in instrumental autonomic conditioning in humans are actually quite unsystematic and confusing. For example, Greene and Nielsen (1966) found that subjects with high scores on a paper-and-pencil test of autonomic awareness showed little, if any, evidence of instrumental GSR conditioning, while subjects with low autonomic awareness scores showed significant conditioning. Thysell and Huang (1968) found good GSR avoidance conditioning without augmented, response-correlated feedback, but no avoidance conditioning at all with augmented feedback. Engel and Hansen (1966) reported conditioned heart rate slowing in subjects who did not guess that heart rate was the reinforced response, but the four subjects in their study who guessed correctly that heart rate decreases kept the reinforcing light on were all non-learners. Also of interest is Engel and Hansen's report of one subject who learned heart rate slowing and indicated that he had kept the light on by thinking of examinations in which he had done poorly and of quarrels he had had with his wife. Similarly, Levene, Engel, and Pearson (1968) found that subjects could learn to increase and decrease heart rate cyclically, in relation to exteroceptive discriminative stimuli, but that one subject who

guessed that heart rate was involved did poorly in acquiring this learned control.

On the other hand, Brener, Kleinman, and Goesling (1969) found that the greater the amount of feedback given to the subject, the better the instrumental heart rate conditioning obtained. Stern (1967), who found little or no evidence of an instrumental conditioning effect in his GSR data, nevertheless reported much evidence of cognitive and cognitive-skeletal strategies. Furthermore, Katkin and Murray (1968) argued that the Engel and Hansen (1966) and Engel and Chism (1967) studies of heart rate slowing and speeding showed merely that voluntary relaxation was the primary technique differentiating between decreases and increases in heart rate, regardless of reinforcement contingencies. Their point illustrates the imprecision that may tend to obfuscate the issue of mediation in instrumental autonomic conditioning. If the subject thinks of some fearful event which elicits an autonomic reaction, and if this is followed closely in time by reinforcement, the tendency to think of fearful events may be strengthened or maintained, assuming that the subject is actually motivated to gain reinforcement. Effective conjuring up of an emotion-producing thought obviously may elicit a variety of sympathetic reactions, such as vasoconstriction, GSR, heart rate and blood pressure increase, etc. This kind of cognitive mediation of an autonomic response is analogous to a person imagining that something hot or electrically charged has touched his hand and, consequently, moving his hand abruptly. If, on the other hand, a person simply thinks of moving his hand and then moves it, cognitive mediation is not ordinarily invoked as an explanatory mechanism. This is because we do not usually think of thinking of skeletal movements before we make them. Yet, even those rare individuals who are able to wiggle their ears must concentrate intensely to demonstrate the response. If a person thinks of relaxation and, consequently, receives reinforcement for heart rate slowing, this kind of "cognitive mediation" may be no different from what is involved in concentrating on controlling a slight hand tremor. It is not at all the same as imagining that one is lying in bed almost asleep or floating calmly in a cool swimming pool. Nor is thinking of generalized "excitement" the same as thinking of almost being struck by a car, although one's heart rate may increase in both cases. Cognitive mediation should be reserved for those instances of apparent instru-

mental autonomic conditioning in which the subject reports thinking of a situation or event which could conceivably elicit the autonomic response, and in which the subject also reports persistence or even increases in the occurrence of such a cognition. When nothing more is meant by cognitive mediation than what is necessary to perform an unusual or rare skeletal response, such as wiggling the ears, nothing is gained by its invocation (unless, of course, the cognition involved in ear wiggling is imagining that one is a bird or a rabbit). Making a GSR, a vasoconstriction, or dilation, slowing or speeding the heart, or increasing or reducing blood pressure or salivation, all may be assumed to be at least as difficult as moving one's ears, and cognizing in the form of scanning for some kind of proprioception is surely to be expected.

As the foregoing discussion clearly shows, the temptation to engage in polemics is almost irresistible. What data there are do not settle the basic argument because data inevitably are subject to differing interpretations. There have now been about 95 published experiments on instrumental autonomic conditioning in humans, with over 90% reporting positive results. Most of the more recent of these studies have included both control and measurement procedures to gain information regarding skeletal, cognitive, or other mediators. One of these recent studies (Lang & Melamed, 1969) involved the successful use of electric shock punishment in eliminating ruminative vomiting in a *nine-month-old infant*. The punishment was triggered by an EMG transducer which picked up indications of reverse peristalsis from the esophagus. There are now three published experiments showing instrumental conditioning of salivation in humans (Brown & Katz, 1967; Delse & Feather, 1968; Frezza & Holland, 1971). In the Frezza and Holland (1971) study, both increases and decreases in salivation were learned. There was some tendency for increases in salivation to be correlated with a tendency toward increased swallowing movements, but it was more likely that the salivation elicited the swallowing than the reverse. More significantly, there were no observable movements correlated with learned decreases in salivation. It is important to point out that humans do not succeed in influencing salivation by deliberately imagining eating succulent foods or lemons, or performing other acts (Feather & Wells, 1966). Perhaps even more cogent to the mediation issue are the data recently reported by Schwartz, Shapiro, and Tursky

(1971) on reward training of heart rate and blood pressure changes. I would like to quote one sentence from their discussion because it presents their conclusions very concisely and, also, because it identifies the problem faced by supporters of a mediation hypothesis, "Man can learn to increase both his blood pressure and his heart rate, lower both his blood pressure and his heart rate, or raise and lower his blood pressure *or* his heart rate [p. 62, italics added]." Furthermore, Schwartz (1971) has now also shown that people can learn to raise their blood pressure while lowering their heart rate *at the same time*, and, although less unequivocally, to lower their blood pressure and raise their heart rate at the same time. It seems to me that mediationists may also have to become cognitive contortionists to deal with data such as these.

I have refrained from presenting any of the evidence obtained in studies of curarized and non-curarized subhumans, although their results are obviously relevant to the question of skeletal mediation in instrumental autonomic conditioning. There are two reasons for this choice. The first is simply that this presentation is focused on instrumental autonomic conditioning in human beings and the addition of the animal work would have required time more appropriately directed to consideration of uniquely human issues (e.g., cognitive mediation, applications to clinical psychology). Second, it turns out that even dramatic effects of instrumental conditioning in deeply curarized rats may be laid to theoretical "central" mediators (Black, 1970). For some, the very idea of instrumentalization of autonomic responses is unacceptable a priori. Since I am suggesting that something resembling stubborn unwillingness may preclude acceptance of the possibility that the law of effect may embrace autonomic as well as skeletal behavior, let me remind you that methodological objections of a somewhat similar type delayed acceptance of the significance of the law of effect for skeletal behavior as well (cf. Osgood, 1953, pp. 380-382). I am alluding to what was once known as the *retroflexive paradox*. I suspect that an unrecognized dualism underlies this strong resistance to accepting the instrumental modifiability of autonomic behavior. The previously quoted remark of Skinner, in which he concluded his argument against the possibility of operant autonomic conditioning by noting that, "If some technique could be worked out to achieve this result, it would be possible to train a child to control his emotions as readily as he controls the

positions of his hands [Skinner, 1953, p. 114]," illustrates my point. Skinner's statement is sensible only under the assumption of *voluntary* control of skeletal behavior, with the capriciousness and free will such an assumption implies. I believe that it is because of this unrecognized free will attributed to skeletal behavior that involuntary, autonomic behavior must be restricted to modifiability only by classical conditioning, that is, mechanically. Exclusion of autonomic responses from the elite domain of the instrumentally conditionable has the function of protecting the unrecognized dualism. Perhaps the influence of Skinner's (1971) *Beyond Freedom and Dignity* will ultimately sweep the ghost of this reverse dualism from autonomic behavior's closet. Surely, if we succeed in purging what Skinner calls "autonomous man" as an explanatory concept in dealing with skeletal behavior, we may also succeed in banishing him, in the guise of an unobservable central mediator, in dealing with the more mechanical autonomic responses.

Basic and Applied Implications

1967-1974

The realization that human autonomically mediated responses may be conditionable instrumentally has obvious implications both for basic conditioning theory and for applied problems in clinical psychology, especially in connection with the treatment of psychosomatic disorders. I will comment only briefly on what I think the basic theoretical implications are and what they are not, so that somewhat fuller treatment of psychosomatic therapy will be possible. A more complete discussion of the basic significance of the instrumental conditionability of autonomic responses would probably be premature at this time anyway, because there are still so many methodological issues to be settled and factual blanks to be filled.

Now that we have good reason to believe that autonomically mediated responses may be conditioned instrumentally, we should not assume therefore that all conditioning is instrumental conditioning, as some have suggested (e.g., DiCara, 1970). In my judgment, that would be at least as great a mistake as assuming that all conditioning is classical conditioning, that is, that the law of effect is trivial. Instrumental conditioning of autonomic responses, to the extent that we now have observed it, is not identical with instrumental conditioning of skeletal responses, to the extent that we under-

stand it. If we learn anything from the discovery that certain autonomic responses yield to instrumental reinforcement, it should be that a more critical approach to our scientific categorizations must be taken. Some responses appear to be more readily conditionable by the method we have arbitrarily devised and called classical conditioning—more readily than they are conditionable by another method arbitrarily invented and named by us. Some responses appear to be more readily conditioned by one or the other of these arbitrarily elaborated methods than are other responses. It is easier to condition a dog to flex a limb by reward training than by classical pairing of a conditioned stimulus and shock, just as it is easier to condition a dog to salivate to a tone by classical pairing of the tone with food than it is to train the animal to salivate to avoid shock instrumentally. These comparisons may be made just as meaningfully *within* either the skeletal domain or the autonomic as *between* the two. That is, it is easier to condition the human vasomotor reflex by reward training than it is to condition the GSR similarly. And it is easier to condition the GSR classically, with shock as the unconditioned stimulus, than it is to condition salivation classically with food as the unconditioned stimulus, in human subjects. Furthermore, it is easier to condition unelicited human GSRs instrumentally than to condition elicited GSRs instrumentally, even using the same reinforcement. And it is easier to condition some autonomic responses with augmented feedback than without, and the reverse is true for others.

We have focused mainly on a single difference between our two traditional conditioning methods, namely, whether the reinforcement is contingent on a response or a stimulus. There are other differences of potential significance which we have largely ignored, and there are differences within each of our arbitrary types which we have ignored as well. What is there about an autonomically mediated response that makes it easier to condition classically than instrumentally, or easier to condition when unelicited than elicited? Having reduced the arbitrary classical-instrumental distinction to a one-bit dichotomy, we are now confronted with the necessity of a complete overhaul, if we expect ever to put the pieces back together again. To me, that is the theoretical significance of instrumental autonomic conditioning.

John Watson said that we may gain or lose our happiness because of behavior our guts lead us into.

Now that we know that our gut reactions are modifiable instrumentally themselves, it may be possible to redefine happiness and unhappiness directly in terms of learned autonomic patterns of reaction. I have recently suggested that the unhappy state known as chronic anxiety may be better represented in instrumental conditioning terms than by the more conventional classical conditioning model (H. D. Kimmel, 1974). Ever since Mowrer (1939) made his seminal translation of Freud's concept of anxiety into S-R language, the tendency to equate it with classically conditioned fear has pervaded our conception of it. Yet, it is obvious that the conditioned fear model is inadequately fitted to clinical anxiety, except perhaps when the anxiety is associated with phobic stimuli. Classical fear reactions are known to extinguish very rapidly when the unconditioned stimulus is removed, but anxiety is persistent. Classical fear reactions are very brief in duration, but anxiety states go on for hours, or days, without abatement. Perhaps even more importantly, classically conditioned fear is a reaction to a stimulus, while clinical anxiety is more often not stimulus bound but tends to be free floating and vague in its reference.

Greene and Sutor (1971) described a study of instrumental GSR conditioning which seems better suited to serve as a prototype of the etiology and maintenance of anxiety, in the light of these deficiencies in the classical fear model. Their subjects listened to music during the conditioning session, but unless unelicited GSRs occurred at least as often as once per 30 seconds, the music would be interrupted by an aversive pattern of one-half second of silence and one-half second of music. The GSR delayed the aversive interruptions for 30 seconds, on a Sidmanlike avoidance schedule. These conditions obtained only while a visual discriminative stimulus, three horizontal dots, were present. When the visual stimulus was changed to three vertical dots, four different control conditions were administered to four subgroups of different subjects. One subgroup simply received uninterrupted music during the control condition, equivalent to the removal of the aversive stimulus in Sidman extinction. A second group received only interrupted music, with the possibility of terminating it or delaying it removed. A third group received a mixture of interrupted and uninterrupted music, resembling the avoidance condition but not response-contingent. And the fourth subgroup re-

ceived response-contingent punishment during the control condition. All but one of the subjects responded more frequently during the avoidance than the control condition. Furthermore, this difference between avoidance and control responding increased from the first five conditioning sessions to the last five in all but one subject. Most significantly, the subjects who had received punishment for unelicited GSRs during the control condition not only showed the greatest difference between responding in avoidance and control periods, but also made the greatest increase in this differentiation from the first to the last five sessions. This increase did not result from a reduction in response frequency during punishment, but to a very large increase in response frequency during the avoidance condition. In other words, the subjects who showed the highest frequency of Sidman avoidance responding were the ones who had an avoidance contingency intermixed with response-contingent punishment. This tendency persisted and grew in strength during the 10-day period of this experiment. Now, a chronically high rate of unelicited GSRs is not tantamount to chronic anxiety, but to the extent that it is a microcosmic analogue of it, Greene and Sutor's study suggests a great deal about how such states may come into existence and be maintained.

Quite a range of psychosomatic ailments have come under instrumental autonomic conditioning's scrutiny in the past few years. As might be expected, most attention has been given to cardiac malfunction. Weiss and Engel (1971) employed instrumental conditioning of heart rate in an effort to control the occurrence of premature ventricular contractions in cardiac patients. All of the eight patients they studied showed some degree of heart rate control, but only five also showed decreases in the frequency of premature contractions. Four of the improved patients maintained a reduced frequency of premature ventricular contractions during several months of follow-up, the longest being 21 months at the time of publication of their report. Engel and Melmon (1968) conditioned more regular cardiac rhythms in patients with several different kinds of cardiac arrhythmias, and DiCara (1970) described a case of successful treatment of a patient with chronic tachycardia by means of instrumental heart rate conditioning. In studies of cardiac malfunction which were less therapeutic than analytical in purpose, Bleeker and Engel (1973) trained six patients with chronic atrial fibrillation and rheumatic heart disease to

slow and speed their ventricular rates differentially. All of the six patients learned this control, even though they were all under digitalis medication at the time of study. Engel (1971) also reported a study of three patients with complete heart block, a condition in which the ventricle behaves as if it is functionally disconnected from the atrium and the atrial-ventricular node. None of these patients were able to learn to speed their ventricles, indicating that, while the intact heart and the innervated atrial-ventricular node ventricle preparation can learn heart rate control, the innervated ventricle alone cannot. One unexpected spinoff from this research on heart function using instrumental conditioning methods was the possible use of this method to unmask latent digitalis toxicity.

Benson, Shapiro, Tursky, and Schwartz (1971) used an operant-conditioning-feedback technique to train seven patients with essential hypertension to lower systolic blood pressure. Six of the seven were able to learn some degree of reduction in systolic pressure within the range of 8 to 34 sessions employed, with the average reduction for the entire group of seven patients being 16.5, which was statistically significant. Beyond this, five of the patients showed clinically meaningful decreases in systolic blood pressure, with one dropping from 213 to 180 and another from 162 to 133. Since these changes were observed only in the laboratory, the therapeutic value of the method remains to be determined, although its promise is considerable. Schwartz (1973) recently identified several of the more significant clinical issues and problems associated with the use of biofeedback and instrumental autonomic conditioning as therapy.

At the close of my article in the *Psychological Bulletin* (H. D. Kimmel, 1967) I expressed the hope that the next few years would provide the theoretical structure required by the growing body of results. As I have tried to show in this presentation, a great deal of additional data has been collected, in both the basic research and applied areas, but only the most preliminary theoretical conjectures have emerged. My own view is that the traditional categories of conditioning must be reexamined and new categorizations developed and evaluated. Perhaps another few years may be all we need; perhaps we will need more than a few years. In either case, the rapidly growing interest and experimentation in the field of instrumental autonomic conditioning, from the not-so-distant past, when it was "not so much imaginary as im-

possible," to the present, when biofeedback machines for home use are being recommended, must go down as a most remarkable scientific about-face.

Aggression in Childhood

Developmental Perspectives

WILLARD W. HARTUP

*Institute of Child Development
University of Minnesota¹*

Although the literature dealing with aggressive behavior in children is extensive (Feshbach, 1970), little actually concerns ontogenetic issues, and very little derives from developmental theory. Among the more significant lacunae in research on aggression development are the following:

1. *For no species do we know from which early motor patterns the components of later aggression are shaped.* From time to time there have been suggestions that the rage reaction (tantrums) may be the wellspring of early aggressive behavior (Hamburg & Van Lawick-Goodall, in press; Munroe, 1955). Tantrums occur early in ontogenesis, they have great capacity for eliciting reaction from the environment (they are noxious), and both the occurrence of tantrums and their behavioral components are sensitive to feedback contingencies (Etzell & Gewirtz, 1967; Goodenough, 1931). Because tantrums produce both positive and negative feedback (parents capitulate to tantrum behavior as well as punish it), these behaviors probably serve as opportunities for the young child to learn the efficacy of aggressive action as well as the efficacy of aggressive inhibition. As yet, however, the contributions of such patterns to aggressive ontogenesis are unknown.

2. *The contexts which serve as origins for aggressive development have not been specified for most species.* Both field research and laboratory

studies (Harlow & Harlow, 1965; Jay, 1968) suggest that the context which accounts for most of the variance in the development of nonhuman primate aggression is rough-and-tumble contact with peers. Conditions allowing for rough play to escalate into aggression and, in turn, to deescalate into playful interaction appear to facilitate the acquisition of two repertoires: (a) an armamentarium of aggressive behaviors and (b) mechanisms for coping with the affect and other outcomes of aggressive interaction. Although Patterson and Cobb (1971) have suggested that peer interaction is also the primary context for aggression development in human children, we can only conjecture that rough-and-tumble play during the preschool years serves the same functions for *homo sapiens* as it appears to serve for the common langur and the other non-human primates.

3. *Age changes in the aggressive activity of human children have been documented in an astonishingly small number of studies* (Feshbach, 1970).

(a) *The form of the behavior.* About all that can be said about age changes in the morphology of human aggression is that, from two through six years of age, there is an increase in the utilization of language in aggressive outbursts. Verbal aggression remains the preferred mode of attacking other humans among elementary-school-aged girls, but the evidence is inconsistent about changes in types of physical attack after the age of six. Again and again, social psychologists come back to Florence Goodenough's (1931) data about age differences in children's angry behavior. She found that

With advancing age, the forms of behavior displayed during anger become more definitely directed toward a given end, while the primitive bodily responses of the infant and young child are gradually replaced by substitute reactions commonly of a somewhat less violent and more symbolic character [p. 69].

Then she added that frequency and duration of "after reactions," including sulking, whining, and

¹ This article is based on an invited address presented at the meeting of the American Psychological Association, Montreal, Canada, August 1973. The paper was completed with financial support provided by Grant 5-P01-05027 from the National Institute of Child Health and Human Development. Brendan Gail Rule, Melynda Mason, Jacques Lempers, Douglas Sawin, and the staff of the Amherst H. Wilder Day Care Centers contributed in various important ways to the research described in this article.

brooding, showed a marked increase after the age of four even though the duration of the violent phases of angry outbursts changed but little during the preschool and the early elementary school years.

Surely it is time to recognize, within a developmental perspective, the functional differences existing among verbal aggressive episodes such as the following: (a) "Don't talk to Rachel. She is the most dumb in the world." (b) "I'm gonna pull that fucking Moira's hair out." (c) "Sucker, get out of here." Similarly, there would appear to be no reason to assume that all acts of physical aggression have common functions. Thus, it is inconceivable that, with increasingly sophisticated social-cognitive functioning, qualitative age changes would not be found in children's aggression in addition to the amount of language used.

(b) *The instigators of aggressive behavior.* The earlier studies (Dawe, 1934; Goodenough, 1931) also contain the only differentiated information in the literature concerning age changes in the elicitors of aggression. Goodenough found that, in infancy, angry outbursts are principally keyed to physical discomforts and needs for attention. During the second and third years, however, such episodes are triggered increasingly by "habit training." Social difficulties with peers emerge at about this time as instigators of angry outbursts, and predominate in the years that follow. Dawe's (1934) study of 200 quarrels occurring in a nursery school also tells us about age changes in the events that elicit aggression: (a) Although possession-instigated quarrels predominated at every age level from 18 months of age through 65 months, 78% of the youngest children's quarrels were instigated in this manner while only 38% of the oldest children's quarrels began in this way. (b) Physical violence increased as an instigator of quarreling from 8% to 27%, and "social adjustment" increased as an instigator of quarreling from 3% to 15% during the period covered. These data hint at two concomitant developmental changes in the functional character of young children's aggression: (a) a relative decrease during the preschool period in straightforward instrumental aggression; and (b) an increase in person-directed, retaliatory, and hostile outbursts. More about these trends later.

4. *Longitudinal studies of individual differences in aggression are few in number.* The famous studies by Kagan and Moss (1962), Bayley and Schaeffer (1964), and Emmerich (1964) stand

nearly alone in elucidating sex-related differences in the stability of aggressive traits. Stabilizing of individual differences in aggressiveness appears earlier in males than in females and seems to be independent of the discontinuities in aggression development mentioned above. Evidence for developmental transformations in the area of aggression is much more tenuous, although the findings reported by Kagan and Moss (1962) are intriguing: Early aggression in girls was predictive of later competitiveness and rejection of feminine sex-typing rather than later aggressiveness. All that needs to be noted here, however, is the general paucity of data on individual differences in aggression development.

Overall, then, data concerning the developmental course of aggression are in short supply. The shortage extends to information about changes in the form of the aggressive acts themselves, the contexts in which aggression originates, the circumstances that trigger aggressive episodes, and stability in individual propensities to respond aggressively across time and circumstance.

A New Study

Three developmental hypotheses concerning children's aggression formed the basis of a new study completed at the University of Minnesota: (1) There is a greater proportion of hostile, "person-directed" aggression relative to "object-oriented," instrumental aggression in the interactions of grade school children than in the interactions of preschool children. (2) Threats to self-esteem lead more frequently to hostile attempts to injure the agent of frustration than to object-oriented aggression, particularly for older children. (3) Blocking is associated primarily with aggression which has instrumental value in gaining or preserving objects, territory, or privileges and in which injury to the other person appears to be a secondary goal. This latter relation, however, should be more consistent for younger than for older subjects.

The conceptual ancestry of these hypotheses should be apparent to anyone familiar with the literature on aggression—it lies in the distinction originating with Feshbach (1964), Buss (1966), Rule (in press), and others between "hostile" and "instrumental" aggression. Basically, this distinction has been used as a means of refining the frustration-aggression hypothesis. According to this line of theorizing, the prerequisites of hostile ag-

gression (i.e., person-oriented aggression) include (a) frustration-produced stimuli which have ego-threatening properties and (b) an inference by the subject that the agent of frustration has behaved intentionally. Other attributions may also be involved in eliciting this form of aggression, but the literature particularly emphasizes the linkage between hostile outbursts and frustrations which involve ego threats or threats to one's self-esteem. In contrast, instrumental aggression, (i.e., aggression which is aimed at the retrieval of an object, territory, or privilege) should be linked to simple goal blocking.

The distinction between hostile and instrumental aggression is far from clean. First, as Feshbach (1970) has pointed out, both instrumental and hostile elements are often involved in the same social interchange. Additionally, this distinction suggests that there is no "instrumental" value to be found in hostile aggression. Clearly, the attempt to restore one's self-esteem by making someone else feel bad is instrumental behavior. Thus, the terminology is imprecise, to say the least. Additionally, Rule and Percival (1971) have raised questions as to whether the psychological processes operating during outbursts of instrumental and hostile aggression are really very different. They found, with adult subjects, that both goal blocking and insult raised their subjects' level of aggression, but these manipulations produced perceptions and attitudes toward the agent of frustration which were virtually indistinguishable. Regardless of whether the aggressor was insulted or frustrated, he reported himself to be more annoyed with the frustrating agent, and indulged in derogation and devaluation of the agent of frustration in similar degree.

On such grounds one may question the ultimate usefulness of the instrumental-hostile dichotomy. Nevertheless, these rubrics serve reasonably well for an attempt to examine the functional properties of children's aggression. First, these concepts may be easily integrated with the existing data. Second, known facts about children's social-cognitive development also suggest that hostile aggression should not be as strongly characteristic of the aggressive activity of younger as of older children. Under the age of six, for example, children have limited capacities for role taking and the generation of inferences and attributions about other people (Flavell, 1968). To the extent that hostile aggression is dependent on attributions about the

agent of frustration (especially his intentions), this type of aggression should be less evident in younger than in older children. Furthermore, self-esteem, valuations of self-competence, and notions about one's status are relatively rudimentary in young children. Just as the young child's conceptions of morality are heteronomous, his conceptions of the dimensions of self-competence and self-worth are unstable. Since reference to self-esteem is a prerequisite to hostile aggression, a lesser proportion of such aggression for younger than for older children would also be expected on these grounds.

Prediction of developmental changes in instrumental aggression is a bit more difficult. Dawe (1934) reported a declining percentage of such aggression in association with increased age. But, should there be a change in the functional quality of the aggression which is elicited by goal blocking as children grow older? Feshbach (1964), Rule (in press), and others have suggested that goal blocking should elicit object-oriented aggression (rather than person-oriented aggression), whatever the individual's age. The data of Rule and Percival (1971), however, suggest that, among adults, blocking produces attitudes and perceptions which are very similar to those produced by insult and derogation. Such an admixture of instrumental and hostile aggression in response to goal blocking should occur, however, only if the individual possesses those cognitive-inferential skills which are prerequisite to the hostile components of the activity. In other words, there is the strong possibility that children's responses to goal blocking are more purely instrumental during the preschool years than during the elementary school years because of the lesser sociocognitive maturity of the younger children. By seven and eight years of age, we would expect considerable inconsistency in the way children respond to blocking (i.e., hostile activity on some occasions and instrumental activity at other times, as well as activity which is "mixed" with respect to its components).

METHOD

The strategy chosen for studying the functional relations outlined above was naturalistic observation. The functions of children's aggression are extremely difficult to study with experimental techniques, and some aspects of children's aggressive functioning are simply not open to experimental attack (e.g., the manner in which children respond to insult).

The study was centered in six groups of children, all in one children's program in St. Paul, Minnesota. All groups, including both preschool children and first- and second-

graders, operated under a common program philosophy. The six groups were located in three different buildings, with one younger and one older group in each building; all of the subjects came from the lower socioeconomic strata of the city. It is important to note that the staff was supervised through a single administrative organization and that the structure of the groups was similar in the case of both older and younger children. All groups were "open" groups in the sense that the schedule permitted the children to have a range of choice among activities and minimal constraints on peer contact. Program activities were not identical—older children simply do not engage in the same play activities as younger children—but gross ecological differences between settings for older and younger children were minimal. One hundred and two children, 56 boys and 46 girls, were enrolled in these groups. Sixty-four were 4–6 years of age; 38 were 6–7 years of age.

Observations were conducted over a 10-week period, using a combination of time and event sampling procedures. Aggressive events were defined as *intentional physical and verbal responses that are directed toward an object or another person and that have the capacity to damage or injure*. Instructions to the observers were to record as much information about each aggressive act as he or she could reconstruct. A sample of one episode is given below:

Marian [a seven-year-old] . . . is complaining to all that David [who is also present] had squirted her on the pants she has to wear tonight. She says "I'm gonna do it to him to see how he likes it." She fills a can with water and David runs to the teacher and tells of her threat. The teacher takes the can from Marian. Marian attacks David and pulls his hair very hard. He cries and swings at Marian as the teacher tries to restrain him; then she takes him upstairs. . . . Later, Marian and Elaine go upstairs and into the room where David is seated with a teacher. He throws a book at Marian. The teacher asks Marian to leave. Marian kicks David, then leaves. David cries and screams, "Get out of here, they're just gonna tease me."

This incident included an initial aggressive outburst followed by counteraggression and continued fighting. Other outbursts, however, were less protracted. Observers were encouraged to use clear language that would not telescope the event and to avoid inferences about the particular intentions, motivations, or feelings of the subjects (Wright, 1960).

The specimen records were then rated on three different occasions by three pairs of coders. The first rating identified all interactions which conformed to the definition of aggression, and the coders isolated the words which described the instigating (antecedent) event and the aggressive act. Agreement for this first rating was 83% for aggressive acts and 92% for antecedent events. A second pair of coders rated the nature of each aggressive act as either hostile (person oriented) or instrumental (object oriented). Their overall agreement was 92%. The third set of coders rated the particular function of the antecedent events and aggressive acts. Nine categories ranging from *bodily injury* and *destruction of property to rejection, derogation, and defiant noncompliance* were used to classify the aggression. Eighteen categories were used to classify antecedent events, but for this report these have been collapsed into three: (a) *blocking* (involving possessions, space, and activity); (b) *bodily contact*; and (c) *derogations* (negative social comparisons, tattling, ridicule, criticism). To preserve independence in assessing the function of the aggressive act and the function of the antecedent event, the coders used two sets of records with either the antecedent event or the aggressive act blacked out. Thus,

if the coder was rating an aggressive act, he had no information about the antecedent event, and vice versa. The functional classification of aggressive episodes and their antecedents was accomplished with an overall percentage of agreement that reached 94%.

RESULTS

For purposes of this presentation, the results will be couched in terms of initial units of aggression, that is, those outbursts which occurred first in an aggressive sequence. Supplemental information will be provided which is based on the entire group of 758 units of aggression observed, even though the interdependence among these units prevents statistical analysis in any depth.

Age. The older children were less aggressive per unit time, overall, than the younger children ($p = .03$). This is the clearest indication in the observational literature that aggression declines in the period immediately after early childhood. The difference was comparable for both sexes. There was a significant Race \times Age interaction ($p = .04$)—among younger children, the rate of aggression for black and for white children did not differ, but the older black children were significantly more aggressive than the older white subjects.

The age difference in total aggression derives primarily from an age difference in the rate of occurrence of instrumental aggression. As expected, this type of outburst occurred significantly more frequently among the younger children ($p = .004$). The significant Race \times Age interaction also derives from instrumental aggression ($p = .007$). That is, there was no race difference in instrumental aggressive activity among the younger children, but the older black children showed more aggression of this type than did the older white children.

The age difference which bears most directly on the hypotheses of the study concerns the proportion of aggressive units which is hostile. Indeed, for those 84 children who initiated aggressive activity, a significantly higher percentage of the aggression was classified as hostile among the older subjects than among the younger subjects ($p = .003$).

Units of aggression were next separated according to two criteria: those elicited by blocking and those elicited by bodily contact. The percentage of each child's aggression which was instrumental was then computed, along with the percentage which was hostile. Blocking produced a significantly higher percentage of instrumental aggression among the younger children than among the older children

($p = .005$), in line with expectations and supporting the notion that there is a greater admixture of instrumental and hostile reactions to this type of frustration for older children. For aggression produced by bodily contact, there was no significant difference between younger and older children in percentage rated as hostile or instrumental.

Examining the data from another viewpoint (and utilizing all of the units of aggression recorded), a functional pattern emerges which is generally consistent with the preceding pattern of results. A clear age difference was found, for example, in the types of hostile behavior which derogation elicits. For younger children, when such antecedents elicit hostile outbursts, half (48%) take the form of bodily injury (hitting) and half consist of reciprocated derogation, threats, and tattling (52%). Among the older children, however, derogation shows a decided tendency to produce reciprocal derogation: only 22% of hostile responses to derogation involved hitting while 78% involved some type of insult or reciprocated threat to self-esteem. A parallel age difference in types of hostile aggression was not found in the aggression elicited by blocking: about 25% of blocking-produced hostility involved derogation, rejection, tattling, and threats for each age group. Thus, when elementary school children are insulted and the insult leads to aggression, the likelihood of insulting retaliation is very great; not so for preschool children. On the other hand, when either older or younger children are blocked, the proportion of insulting hostile reactions does not vary with age.

Sex. Earlier, it was noted that age was not involved in any interactions with the gender variable insofar as the sheer incidence of aggression was concerned. It will come as no surprise, however, that male subjects were more aggressive totally than the females ($p = .01$). This difference was primarily due to a sex difference in the incidence of hostile aggression ($p = .03$); no significant sex difference was obtained in the rate of occurrence of instrumental aggression. Most important of all, none of the functional analyses, that is, those relating the nature of the aggressive outburst to the nature of the antecedent, have revealed significant sex differences. Thus, there is no evidence that boys and girls are differently "wired" with respect to the operation of hostile and instrumental aggression. Such differences were not expected, and the data confirm those expectations.

Race. A similar situation prevails with respect

to race. As noted, more frequent total aggression was observed among older black children than among older whites, owing primarily to the higher incidence of instrumental aggression in the former group. The validity of this finding cannot easily be questioned: There was no reference to race differences in the instructions to observers. Moreover, such differences were in no way related to the purpose of the research; the analyses were conducted only because of their obvious necessity. Indeed, the only way in which these findings could have been produced by observer bias is through more subtle racist stereotypes (the observers were white). But here, too, the more critical race differences would be those relating to the functional properties of the aggression in the interactions of the children. As with sex, no significant differences were found. The patterning of antecedents for hostile aggression and the elicitors of instrumental aggression were not different for our white and black samples.

CONCLUSION

These results lend support to two hypotheses: (1) The developmental course of human aggression may be best understood by means of a differentiated "functional analysis" of the problem. (2) The distinction between instrumental and hostile aggression is heuristically valuable for studying the functions of aggression in early childhood even though it may have more limited usefulness in studies of adolescent or adult aggression.

What is meant by the word *function* in the context of this article? Simply put, the word implies the question, How does it [aggression] work? Answers to this question may be sought from many different vantage points, using many different levels of analysis. One type of analysis might involve the generation of mathematical relational statements between levels of brain stimulation and differentiated aggressive outbursts; other analyses may concern the long-term biological consequences of aggression—that is, whether it serves to maintain an individual's genes in the population. Still other types of functional analysis might concern relations between specific instigating stimuli and the qualities of aggression in particular individuals or groups and how these vary in accordance with the maturation of those response capabilities necessary for a specific type of aggressive display. Each of these functional perspectives is based on the assumption

that understanding how aggression "works" requires knowledge of how the specific aggressive outburst fits into the complicated nexus of events that precede and follow it (Hinde, in press). To this end, the ontogenetic history of the individual and the biological-evolutionary outcomes of the activity must be taken into consideration, as well as stimuli which function as "instigators," "goals," or "reinforcers" in individual behavioral sequences. To specify aggressive functions at only one level of analysis is to risk a myopic conception of the problem like that of the elephant produced by the blind man who only touches the beast's trunk.

Research such as that reported here points the way toward a more complete functional analysis of aggression in children's social interaction. The data, however, are descriptive and do not directly elucidate the relation between social-cognitive processes and age changes in aggression. Do changes in the child's use of attributions about intent and the developmental events mirrored in the observational data emerge in parallel sequence? If so, is there a systematic functional relation between advances in social cognition and changes in aggressive morphology and elicitation? These are the questions to which this work brings us.

A Survey of Behavior Modification Training Opportunities in APA-Approved Internship Facilities

JAMES H. JOHNSON *Division of Child Psychiatry
University of Texas Medical Branch¹*

PHILIP H. BORNSTEIN *University of Montana*

Data from several sources indicate growing interest in behavioral approaches to treatment within the profession of clinical psychology. Ernst (1971) demonstrated the reality of this behavioral "movement" by citing an increased number of publications in the area. Benassi and Lanson (1972) also reported a rapidly increasing number of colleges and universities offering formal coursework in behavior modification.

Although it appears that opportunities exist for graduate training in behavior modification, detailed information is currently unavailable regarding opportunities for such training at the internship level. The purpose of the present research was therefore twofold: (a) to provide prospective interns with information regarding facility-specific training opportunities in behavior modification and (b) to ascertain whether internship facilities, in general, can provide training experiences meaningfully related to this aspect of graduate education.

It should be emphasized that the present survey was not intended to be evaluative in any sense. The listing of the presence or absence of opportunities for training in behavior modification in this article should in no way be construed as an evaluation of the overall adequacy of individual

training programs. It might also be noted that the reporting of opportunities for training in behavior modification does not provide information regarding the *quality* of training within an individual program.

Method

A questionnaire designed to assess behavior modification training opportunities and interest was sent to the clinical training directors of 110 APA-approved internship training facilities in psychology, as listed in the December 1972 issue of the *American Psychologist*. In addition, a cover letter was provided which briefly explained the purpose of the study. The questionnaire consisted of the following 10 questions:

1. How many psychologists are currently on your training staff?
2. Are there one or more psychologists on your staff whose primary area of interest involves the teaching, research, and/or practice of behavior modification? If yes, how many? Degree status?
3. Does your training program at present offer any didactic training in behavior modification (e.g., a formal course or seminar devoted to behavior modification)? If yes, is this required or optional?
4. Do interns at your facility currently have the opportunity to practice techniques of behavior modification while working directly with some patient population?
5. Do interns at your training facility currently have the opportunity to receive supervision in the practice of behavior modification by someone experienced in this area?
6. How many hours per week does your average intern spend in the following behavior modification activities: Direct patient contact? Supervision in the practice of behavior modification? Didactic training?
7. Please rate on the following scale the degree to which your present interns, as a group, seem to show interest in the area of behavior modification:

LITTLE INTEREST

1 | 2 | 3 | 4 | 5 | 6 | 7

GREAT INTEREST

8. Are your present interns, as a group, generally more or less interested in the practice of behavior modification than those interns of five years ago?

¹ The research reported here was funded by the Division of Child and Adolescent Psychiatry, University of Texas Medical Branch at Galveston. The authors are grateful to L. G. Hornsby, MD, Chief of the Division, for his support of this project; Charles O. Gaston, Director of Internship Training in Clinical Psychology, for his help in constructing the questionnaire; Alan S. Appelbaum, for his critical reading of the original manuscript; and John E. Overall, for his helpful suggestions during the revision.

Requests for reprints should be sent to James H. Johnson, Division of Child Psychiatry, University of Texas Medical Branch, Galveston, Texas 77550.

9. In describing the orientation of your department, would you describe it as: A. Analytic, B. Behavioral, C. Existential, D. Rogerian, or E. Other (Specify)?

10. Any additional comments regarding behavior modification experiences at your facility?

Approximately one month after the mailing of the questionnaire, a follow-up letter, an additional questionnaire, and a stamped, self-addressed envelope were sent to facilities not yet responding to the first questionnaire.

Results

A total of 103 responses were received from the 110 training facilities sampled. Three of the facilities, although responding by letter, did not fill out the questionnaire, indicating that the questionnaire did not lend itself to describing their training program. Thus, the present findings are based on the 100 completed questionnaires which were returned.²

Table 1 presents facility-specific information related to training opportunities in behavior modification. Column 1 lists the names of training programs completing the questionnaire. Column 2 reports the number of psychologists on the staffs of training programs. Column 3 indicates the general departmental orientation. Column 4 provides information regarding the presence or absence of a behavioral psychologist on staff. The number of behavioral psychologists is listed in parentheses if more than one. The degree status of those staff members is also indicated. Information in Column 5 indicates whether the program offers formal didactic training in behavior modification and whether this training is required or optional. Columns 6 and 7 provide information regarding facility-specific opportunities for the practice and supervision of behavior modification activities.

Table 2 presents cumulative information related to training opportunities in behavior modification. Column 1 reports the percentage of programs having one or more behavioral psychologists on staff. Column 2 indicates the percentage of programs offering didactic training in behavior modification. The percentages of training programs that reported offering opportunities for the practice and supervision of behavior modification activities are indicated in Columns 3 and 4, respectively.

With regard to degree of intern interest in be-

havior modification, as perceived by training directors, a mean rating of 3.9 was obtained for the 97 programs responding to the question. In comparing present interns, as a group, to interns of five years ago, 73% indicated more intern interest in behavior modification, 18% indicated the same level of interest, and 9% reported less interest ($N = 92$). Data pertaining to Question 6 are not included in the results due to the difficulty many respondents reportedly experienced in answering the question as stated.

Discussion

The overall results of this survey clearly indicate that opportunities do exist for clinical training in behavior modification at the internship level, but as might be expected, such training opportunities vary considerably from one training facility to another.

A number of comments by training directors give further information concerning the place of behavior modification in internship training programs. These statements range from those indicating enthusiastic acceptance of a behavioral approach to those indicating that behavior modification plays a negligible role in the training of interns. One seemingly widely held view, even among those agencies offering behavior modification training opportunities, appeared to reflect the belief that the psychology intern should be trained as a "generalist" not expert in all areas but exposed to all the mainstream of clinical psychology." Statements such as this suggest that although behavior modification training may be viewed as important, it is often perceived as only one aspect of the training necessary for a well-rounded clinician. Other training directors indicated that they viewed behavioral approaches in a somewhat restricted sense, (e.g., "we see behavior modification as a technique, not as a theory of personality"). A number of respondents indicated growing staff interest in the area, suggesting more emphasis was being placed on this approach from year to year.

In summary, it would appear that internship facilities, like graduate departments of psychology, do provide opportunities for subdoctoral training experiences in behavior modification and that intern interest in behavioral approaches, although rated as moderate, is on the upswing. The findings of this study in conjunction with those reported by Benassi and Lanson (1972) suggest that behavior

² Three additional completed questionnaires were received after the preparation of the article and construction of Table 1. Data pertaining to these three programs are not included in the results.

General Convention Information

Deadline, August 1, 1974

1. Please indicate those APA divisions to which you belong (See below for list of divisions).
Check your most senior status regardless of whether you belong to a division.

None

2. Please indicate the number of persons who are accompanying you to this Convention but who are not completing a registration form and are not accounted for on another registration form. Adults Children

How many of them are planning to attend any meetings?

3. Please provide the address to which the convention badge is to be mailed. Be sure to fill in this space even if it is the same as the information given elsewhere on this form.

Street Address: _____

City, State, Zip Code: _____

Registration Fee Status (check one):

\$30: ☐ Nonmember\$20: ☐ APA Member, Fellow, Associate ☐ Foreign Affiliate ☐ High School Teacher AffiliateExempt: ☐ APA Dues-Exempt Member ☐ Student ☐ Nonmember Invited Participant ☐ Nonmember Spouse Dependent of Registrant

Badge Information (Please Print):

Institution/Company Affiliation: _____

City and State: _____

PLEASE PRINT (CLEARLY) NAME BELOW FOR VISIBLE LOCATOR

Title	Last Name	First Name	Initial

This card and these fees are only applicable for advance registration prior to August 1, 1974. After that date advance registration cards received in the APA Central Office will be returned and those who have not yet registered will have to do so on site in New Orleans. If possible use this card rather than photocopied forms. Use another card for additional persons who wish to register. Additional cards can be obtained in any issue of the *American Psychologist* from April through July.

PLEASE COMPLETE BOTH SIDES OF THIS FORM.

Convention attendees are urged to register for the meeting in advance. Not only will advance registration assist APA in planning for the meeting but advance registration represents a saving to the registrant. At its January 18-20, 1974 meeting, the APA Council of Representatives approved the following registration fees for the 1974 Convention:

For Those Registering in Advance Prior to August 1, 1974:

\$30 Nonmember

\$20 APA Member, Fellow, Associate, Foreign Affiliate, High School Teacher Affiliate

For Those Registering On-Site in New Orleans:

\$35 Nonmember

\$25 APA Member, Fellow, Associate, Foreign Affiliate, High School Teacher Affiliate

Send completed form and check for registration fee to:

American Psychological Association
1200 17th Street, N.W., Room 601
Washington, D. C. 20036

Make checks payable to APA.

List of divisions for Question 1 on registration form:

- 1 General, 2 Teaching, 3 Experimental, 5 Evaluation and Measurement, 6 Physiological and Comparative, 7 Developmental, 8 Social and Personality, 9 SPSS, 10 Psychology and the Arts, 12 Clinical, 13 Consulting, 14 Industrial, 15 Educational, 16 School, 17 Counseling, 18 Public Service, 19 Military, 20 Adult Development and Aging, 21 Engineering, 22 Rehabilitation, 23 Consumer, 24 Philosophical, 25 Experimental Analysis of Behavior, 26 History of Psychology, 27 Community, 28 Psychopharmacology, 29 Psychotherapy, 30 Hypnosis, 31 State Psychological Association Affairs, 32 Humanistic, 33 Mental Retardation, 34 Population, 35 Psychology of Women.

Please fill out this form in COMPLETE detail, particularly ARRIVAL and DEPARTURE dates, and type of ACCOMMODATIONS.

SEND APPLICATION AS SOON AS POSSIBLE to address shown at bottom of page to insure desired accommodations at convention rates. DEADLINE August 1, 1974.

Sugar Bowl . . . Superdome, finished or unfinished . . . topless dancers . . . voo-doo.

And that is where the 1974 Convention of the American Psychological Association will be held. The dates of the Convention are **August 30 through September 3**. While August is not the ideal time to be in New Orleans, the attractions of the city should compensate for the heat and humidity. Meetings are scheduled in the Fairmont Hotel, the International Hotel, the Marriott Hotel, the Monteleone Hotel, the Royal Orleans Hotel, and the Rivergate Exhibition Center. The bulk of the Convention program is scheduled between 9:00 a.m. and 6:00 p.m. during the five days of the meeting. Because hotels are fairly close to one another, APA is not planning to run a shuttle bus among the hotels. Public transportation buses run up and down Canal Street every few minutes at a cost of 15 cents per person.

Canal Street, New Orleans' main thoroughfare, separates the French Quarter from the business district and uptown area of the city. There are historical

sights, shops, nightclubs, and restaurants within the French Quarter. In order to sample the cuisine in local restaurants it would be wise to make reservations for all meals. A handy reference on inexpensive and good restaurants is *The New Orleans Underground Gourmet* by Richard H. Collin.

Transportation from the New Orleans International Airport to the downtown area is available by taxicab or limousine. It takes about 30 minutes to make the trip. The taxicab fare is approximately \$9 plus tip for one to three persons; there is an additional charge of \$3 per person for more than three. Limousine service is available directly to the hotels at \$3 per person. Public transportation is also available from the airport for a fare of 35 cents, but it may be necessary to transfer to another bus within the city in order to get directly to your hotel. See you in New Orleans!

Housing

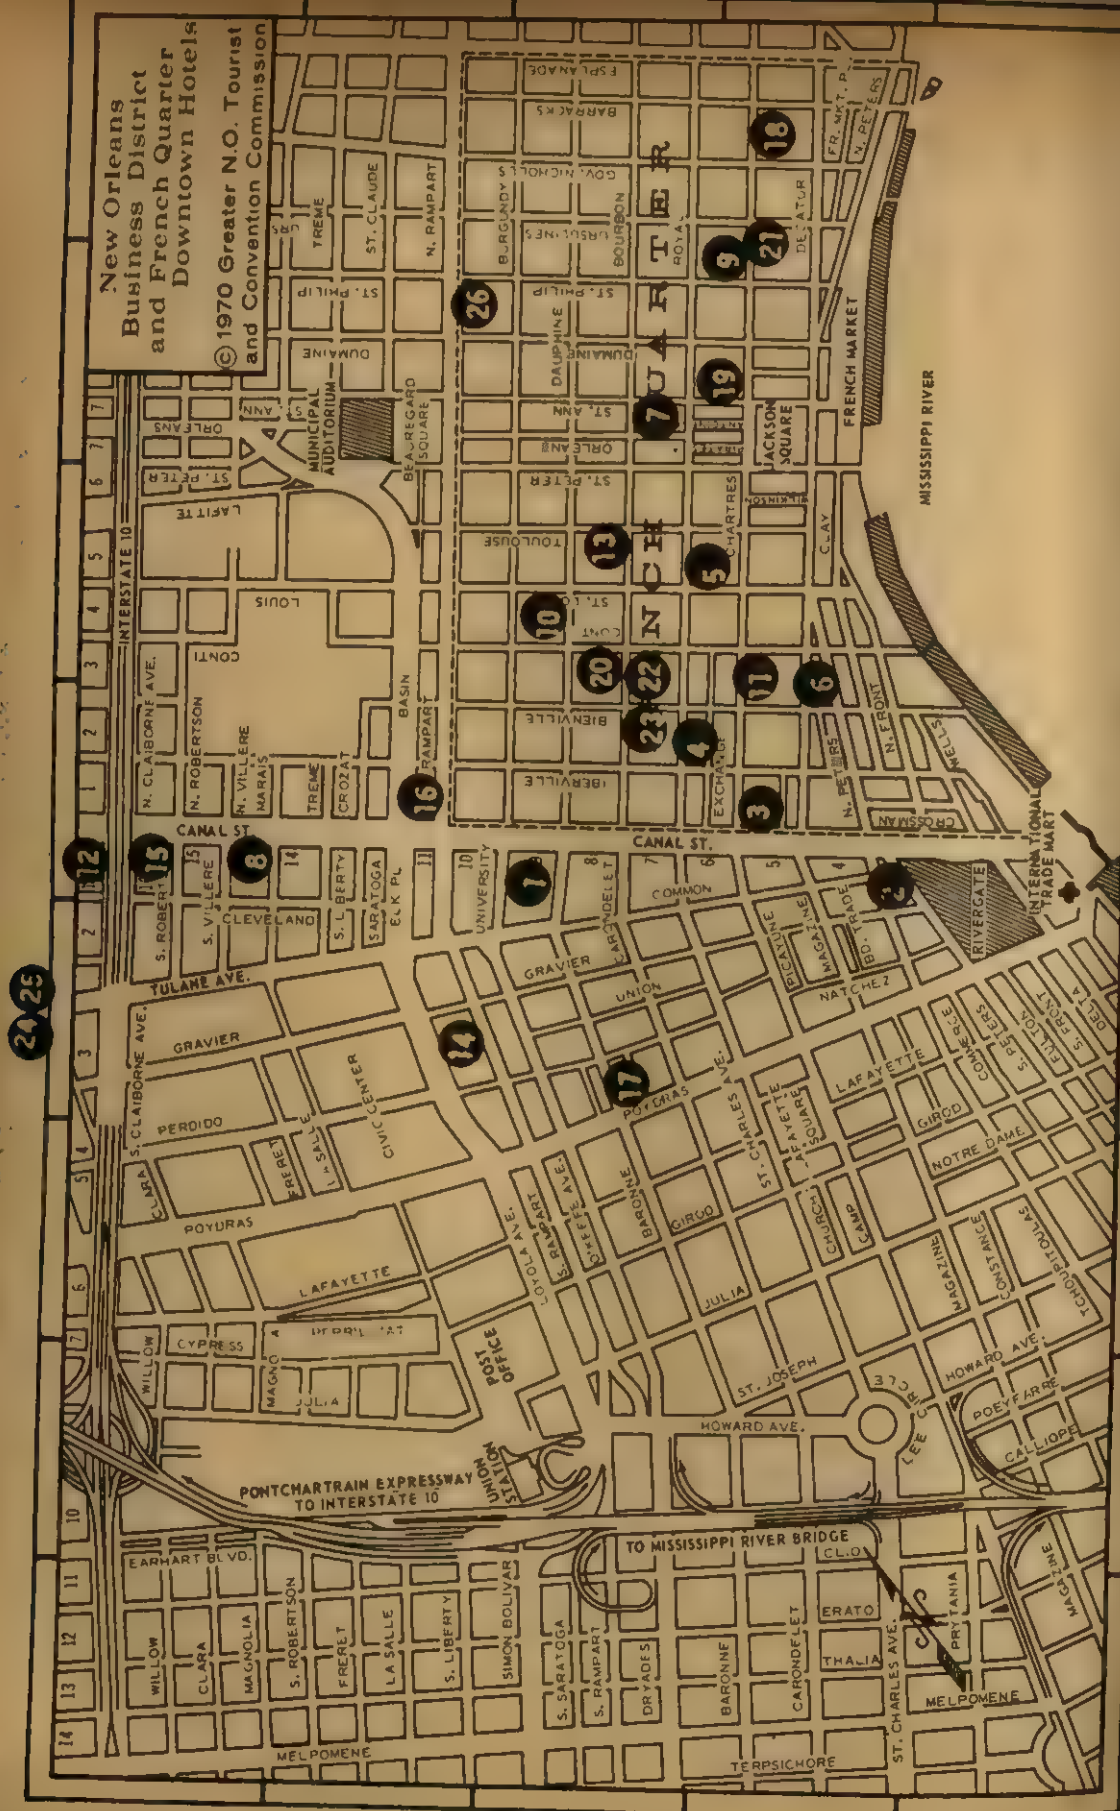

In cooperation with APA, all of the hotels have set aside, at guaranteed rates, substantial blocks of rooms. These hotels have guaranteed rates for the Convention only when registration is made through the APA Housing Bureau on the official Hotel Reservation Form. Also, these rates are guaranteed only when the Advance Registration Form and Hotel Reservation Form are returned *prior to August 1, 1974*. After August 1, every effort will be made to assign rooms at the guaranteed rate, but such assignments cannot be certain, and it is quite unlikely that late requests can be honored.

Members should also bear in mind that with the large number of rooms used, some members may not be assigned a room in the specific hotel they requested nor the type of room at the rate requested. It is advisable to return the Advance Registration Form and the Hotel Reservation Form as early as possible. These forms appear right before this section.

All housing forms are sent from the Central Office to the New Orleans Convention Bureau for room assignments. We anticipate a three- to four-week lag between receipt of request in the APA office and your receiving confirmation from the hotel. If after four weeks you have not heard from New Orleans, please contact di-

and Convention Commission

rectly the New Orleans Convention Bureau, 334 Royal Street, New Orleans, Louisiana 70130.

Wheelchair Accessibility

To facilitate making hotel reservations for those people concerned with wheelchair accessibility, Division 22, the Division of Rehabilitation Psychology, compiled the following information on the accessibility of some of the Convention hotels. Wherever possible, the information has been corroborated by site visits made by knowledgeable persons. Detailed information about the accessibility of various churches, restaurants, museums, and stores may be obtained by writing for a free copy of *Guide to New Orleans for the Handicapped* from Louisiana Chapter, National Society for Crippled Children and Adults, Inc., 843 Carondelet Street, New Orleans, Louisiana 70130.

Rivergate Exhibition Center

Main entrance: Accessible
Restrooms: Accessible
No sleeping rooms

International Hotel

Main entrance and elevators: Accessible
Public restrooms: Accessible
Sleeping rooms: Two meet accessibility requirements and must be requested.

Monteleone Hotel

Garage entrance and three elevators: Accessible
Public restrooms: Accessible
Sleeping rooms: Hotel has 56 accessible sleeping rooms which must be specifically requested. They are rooms on the fifth floor in the following series: 53, 56, 57, 58, 63, and 69.

Fairmont Hotel

One of the main entrances to the hotel is ramped.
Public restrooms: Women's—accessible
Men's—inaccessible
Sleeping rooms: Inaccessible

Royal Orleans Hotel

Main entrance: Assistance available to negotiate the steep ramped entrance from garage and staired main entrance.
Elevators: Accessible
Public restrooms: Accessible
Sleeping rooms: Inaccessible

Marriott Hotel

Main entrance: Accessible
Elevators: Accessible
Public restrooms: Inaccessible
Sleeping rooms: Inaccessible

Royal Sonesta Hotel

Main entrance: Accessible
Elevators: Accessible
Public restrooms: Inaccessible
Sleeping rooms: Inaccessible

Persons requesting wheelchair-accessible accommodations should check the appropriate box on the Hotel Reservation Form as well as indicate the hotel and type of accommodation requested.

Registration

Convention attendees are urged to register for the meeting in advance. Not only will advance registration assist APA in planning for the meeting, but advance registration represents a saving to the registrants as well as the opportunity to obtain desired hotel space and rates. At its meeting on January 18–20, 1974, the APA Council of Representatives approved the following registration fees for the 1974 Convention:

For those registering in advance (prior to August 1, 1974):

\$30—Nonmember
\$20—APA Member, Fellow, Associate, Foreign Affiliate, High School Teacher Affiliate

For those registering on-site in New Orleans:

\$35—Nonmember
\$25—APA Member, Fellow, Associate, Foreign Affiliate, High School Teacher Affiliate

24. Tamanaca (Best Western) Downtown Motel
25. Thunderbird (Quality Inn)
26. Vieux Carre Motor Lodge

Students and other authorized exemptions from these fees appear on the Advance Registration Form.

The convention badge, with name and institutional affiliation, will be mailed in advance of the Convention to those who preregister. Advance registrants will need only to obtain a badge holder at the APA registration area in New Orleans to complete the procedure—thus avoiding possible delays.

Complete member and nonmember registration facilities will be maintained at three locations—the Fairmont Hotel, the Marriott Hotel, and the Rivergate Exhibition Center—according to the following schedule:

Thursday, August 29, 3:00 p.m. to 9:00 p.m.

Friday, August 30, 8:30 a.m. to 5:30 p.m.

Saturday, August 31, 8:30 a.m. to 5:30 p.m.

From Sunday, September 1 through Tuesday, September 3, registration facilities will be available only at the Rivergate Exhibition Center. Hours will be 8:30 a.m. to 5:30 p.m. on Sunday and Monday; 8:30 a.m. to 12 noon on Tuesday.

Placement

The APA Convention Placement Office will be located in the Rivergate-South Hall. Hours will be from 9:00 a.m. to 5:00 p.m., August 30–September 3, except 1:00 p.m. closing day. Fees required are as follows:

Applicants—\$2 for reproducing (1) availability information. \$3 for use of Convention Placement facilities includes a copy of the *Position Openings Bulletin*. (Nonmembers will be charged \$20 for use of Convention Placement facilities.) July 19, 1974, is the deadline for applicant listing. Appropriate fee must accompany listing.

Employers—\$5 for reproducing (1) Job Description. \$10 for use of Convention Placement facilities includes a copy of the *Availability Notices Placement Bulletin*. July 26, 1974, is the deadline for employer listing. Appropriate fee must accompany listing.

Employers: Please note the addition of the GENERAL OPENINGS category to be used by organizations hav-

ing widespread needs for psychologists who may be recruited through a central office.

Prelisting in the more widely distributed printed booklet is encouraged, but Xerox forms will be available for on-site listing. The forms, accompanied by the appropriate listing fee, must be received by the date indicated above. Please do not include the Convention Placement facilities fee which will be collected ONLY when you register at the Placement Office. After the above date, Xerox forms will be available for listing, and requests should be directed to the address below.

A complete set of applicant availabilities will be available to employers: \$15 for each category—please indicate choice. After the Convention, order from the Convention Placement Office, American Psychological Association, 1200 Seventeenth Street, N.W., Washington, D.C. 20036.

Mail orders for the printed *Availability Notices Placement Bulletin* and the *Position Openings Bulletin* are \$1.50 per copy (available August 7). Your check (no billing) may be sent to the above address.

Convention Personnel

You may wish to contact one or more of these people before or during the Convention:

Board of Convention Affairs: Carl N. Zimet, Division of Psychology, University of Colorado School of Medicine, Denver, Colorado 80220.

Convention Manager: Theodore G. Driscoll, Jr., Driscoll and Associates, 7109 Masters Drive, Potomac, Maryland 20854.

Assistant for Convention Management: Candy Won, American Psychological Association, 1200 Seventeenth Street, N.W., Washington, D.C. 20036.

Convention Placement Office: Jim Beauter, American Psychological Association, 1200 Seventeenth Street, N.W., Washington, D.C. 20036.

Please Note

Meetings for Divisions 19 and 21 will be located in the *Monteleone Hotel* rather than the Royal Orleans Hotel as noted in the convention insert.

Convention Child Care Service

Provision has been made for a professional child care service during the 1974 Convention. CON-SERV has been engaged and will offer an extensive program.

Parents desiring to use child care facilities must preregister no later than July 15, 1974. To preregister, complete the form at the bottom of this page. Please note that upon filing of the preregistration form and payment of the advance deposit as indicated on the form, CON-SERV will provide complete detailed information about the services offered and final registration materials necessary to plan for your children's comfort and safety. If for any reason your plans change, the deposit will be refunded in full if CON-SERV is notified of cancellation by August 10.

Some of the essential features of this service, as planned, are indicated below:

- The facility will be located in Braniff Place Hotel and will be open from 8:00 a.m. to 6:30 p.m., August 30–September 3, 1974. While the cost will be about \$1.50 per hour per child, APA will subsidize \$.75 of this cost. Hence, the cost to parents during the daytime will be \$.75 per hour per child.
- If there is sufficient need, the facility will remain open after 6:30 p.m. until 12 midnight to accommodate

parents who may wish to leave their children in the facility during evening hours. The parents will bear the full cost during these hours. If the need for evening child care does not justify keeping the facility open after 6:30 p.m., personnel at the facility will make every effort to help individual parents locate qualified babysitters to stay with children in their hotel rooms for those who might need this service. In any event, every effort will be made by CON-SERV to assist parents with evening child care arrangements.

- During the regular daytime hours, a variety of optional tours will also be offered at modest cost to parents. APA will subsidize part of the cost to the extent of \$.75 per hour per child as though the child were in the facility.
- In order to evaluate the child care services at past conventions, the Task Force on Convention Child Care would like you to answer the following questions: (a) What was your general reaction to past child care facilities? (b) What was the least-liked aspect? (c) What was the most-liked aspect? (d) What was needed and not provided? Please attach your answers to the preregistration form.

Preregistration Form: Child Care Service—APA Convention New Orleans, Louisiana, August 30–September 3, 1974

Preregistration form must be returned no later than July 15, 1974.

Name of Parent or Guardian: _____

Street Address: _____

City, State, Zip: _____

Name(s) of children to be registered in the child care facility:

Name	Age
_____	_____
_____	_____
_____	_____

If your child has a specific problem or handicap that we should be aware of, that is, speech impediment, retardation, epilepsy, etc., please let us know so that we may make the necessary provisions. _____

Please check this box if you are interested in tour information for your child

Signature of Parent or Guardian

Please return this form to Ms. Diane Snow, Con-serv, 1318 Arabella Street, New Orleans, Louisiana 70115, and enclose a check in the amount of \$7.50 for one child or \$15.00 for two or more children as listed above. Make checks payable to "Con-serv." Indicate amount enclosed:

\$ _____

NOTE: This is only your preregistration form. Upon receipt of this form you will be furnished complete registration materials.

Newly Released

standards

FOR EDUCATIONAL & PSYCHOLOGICAL TESTS

This revised document reflects changes in the social climate as well as technical and theoretical advances since publication of the 1966 *Standards*. Developed under a grant from the Russell Sage Foundation by a joint committee composed of members from the APA, the American Educational Research Association, and the National Council on Measurement in Education, the revised guidelines are directed equally to test developers and users.

Standards for—

Washington, D.C. 20036**

Employers of Psychologists:

If you have or anticipate openings for psychologists, you may wish to list them with the APA Convention Placement Service. The Job Description Form below is for this purpose. Additional copies supplied upon request.

A service fee of \$5.00 per insertion will be required for listing in the **Convention Placement Bulletin**. FEE MUST ACCOMPANY COPY—no billing by APA—DEADLINE JULY 26. If you recruit at the Convention, an additional \$10.00 fee will be required for use of the Placement Office facilities. This fee payable ONLY when you register at the Placement Office.

The FINAL FORM of your job description below will be the actual copy used in photo offset printing of the **Convention Placement Bulletin**. The box thereon is the maximum space usable. An illustration and a work form are provided for your guidance. Only clean typed copy within the boundary on the FINAL FORM will be accepted for publication. Please list your job data of the kind and in the order illustrated. Do not skip any lines. Thank you.

ILLUSTRATIVE FORMAT

	Job title (caps)	Number of openings	Degree required or preferred	Date job begins
Starting salary & basis	CLINICAL PSYCHOLOGIST: 1 PhD or MA lacking only PhD thesis. Now or Jan. 1975			
	\$14,000-16,000/12 months. Internship + 2 yrs experience in mental health setting; teaching experience desirable.			
Duties	Teach intro clinical psych to interns, nurses in university hospital: perform diagnostic & therapeutic activities in univ mental health clinic; do research in area of own interest as time allows. Joint appointment in clinic & psych dept possible.			
Employer name & address	JA Smith, Chairman, Dept Psych, Univ of Erie, Centerville 3, NY. See him Aug. 30, 31, Sept. 1, 2, am & pm, or write.			

Tentative interview schedule (Aug. 30-Sept. 2, am & . or pm, Sept. 3 until 1 pm are the available times).
If none, enter name to whom inquiries may be mailed.

WORKING COPY—Draft your job description here, following the above guidelines.

times higher than the estimated general population rate of 1:700.¹

Table 4 (Chromosome Surveys of Criminals) also reveals a confounding of studies which did and did not select for height. Without having tried to check carefully every single citation in this table, we were able to determine that several of the studies had screened only tall subjects (e.g., Falek, Craddick, & Col-lum, 1970; Marinello, Berkson, Edwards, & Bannerman, 1969; Melnyk, Derencsenyi, Vanacek, Rucci, & Thompson, 1969; Welch, Borgaonkar, & Herr, 1967). However, Jarvik et al. (1973) made no distinctions between these studies; nor did they even provide any information about the height selection factor.

There are still other problems with Table 4. We have already indicated the differing prevalence rates obtained for regular mental hospitals and penal institutions, and the distinctly higher rates rather consistently found in security hospitals (namely, institutions for mentally disordered offenders). In Table 4, Jarvik et al. included at least five studies which pertain to *mentally disordered offenders* (namely, Abdullah, Jarvik, Kato, Johnston, & Lanzkron, 1969; Melnyk, Derencsenyi, Vanacek, Rucci, & Thompson, 1969; Nielsen, Stürup, Tsuboi, & Romano, 1969; Nielsen, Tsuboi, Tuver, Jensen, & Sachs, 1969; Welch, Borgaonkar, & Herr, 1967). Not only is such lumping together of studies misleading, but in addition, the reader is not even informed about the types of studies and populations included in this table.

Finally, we wish to address ourselves to the repeated statements by Jarvik et al. linking the XYY chromosome complement and aggression. The title of their article ("Human Aggression and the Extra Y Chromosome") as well as numerous other

statements suggest that males with 47,XYY karyotypes tend to be rather aggressive. For example, references were made to the "unusually aggressive temperament," the "dominant feature" of "excessive episodic aggressiveness," and the "powerful aggressive tendencies" of many XYY males. At one point the authors stated: "Since the XYY genotype has been associated with antisocial behavior, it would be reasonable to expect a higher frequency of this disorder among persons who have come in conflict with the law than among men in general [p. 679]." And, again, the authors asserted: "The data available so far, therefore, provide strong presumptive evidence for an association between criminal behavior and the extra Y chromosome [p. 679]."

To begin with, the data to which these authors alluded do *not* link the XYY karyotype with either "antisocial behavior" or "criminal behavior." The studies in question pertain to offenders who have been incarcerated in various institutions. This latter group represents a small and highly selected sample of all those convicted of crimes; those convicted of crimes represent a small fraction of all those who come to official attention for criminal behavior. Furthermore, not all of the criminal behavior comes to official attention, and not all behavior that may be considered "antisocial" is necessarily defined as "criminal" (e.g., see Shah, 1972). To the extent that several studies do suggest a higher prevalence rate for the XYY condition among institutionalized offenders, the increased risk which may be incurred pertains to certain types of *institutionalization*—and not for antisocial or criminal behavior as such.

Even though Jarvik et al. made numerous references to the "aggressiveness" and the "impulsive violence" of XYY males, they failed to provide any clear or convincing evidence to support such assertions. They did cite some highly publicized instances of XYY males charged with murder. It would have been inter-

esting to know, for example, if the XYY males in various mental, penal, and security hospitals had increased rates of involvement in violent crimes, and if they had displayed more violent behavior toward other patients and staff, in reference to comparable groups of 46,XY males in the same institutions. Such information was not provided by the authors even though it is available in the literature.

For example, in preparing a recently completed comprehensive review of the XYY chromosome complement (Borgaonkar & Shah, in press), we were able to report on a number of studies which provide data that seriously challenge assertions about the "unusual aggressiveness" of XYY males. These data pertain to psychological test indices as well as to aspects of institutional adjustment. See, for example, Hope, Phillips, and Loughran (1967); Little (1968); Price and Whatmore (1967a, 1967b); and Street and Watson (1969).

We would not assert that the data thus far available clearly indicate a lack of aggressive and violent behavior among XYY males as compared to control subjects from the same institutions. However, these data do lead us to question the assertions made by Jarvik et al. about the unusual aggressiveness of XYY males. Based on presently available data, it would appear that, in general, XYY males have been falsely stigmatized as a group.

In closing we wish to point out that we are *not* trying to explain away biologically determined factors in human behavior; nor are we inclined to explain behavioral phenotypes entirely on the basis of environmental influences. Indeed, we have had occasion to point out that behavioral and social scientists have typically displayed an environmentalist bias (e.g., see Shah, 1972; Shah & Roth, in press). However, what we wish to emphasize is that the issues discussed by Jarvik et al. cannot and should not be posed in an either/or fashion. The "basic question," we would suggest, pertains to

¹ On the basis of more recent estimates (Borgaonkar & Shah, in press), it would appear that the prevalence rate for the general population may be even lower, namely, in the range of 1 XYY in 1,500-3,000 males.

the need for more sophisticated conceptualization of the aforementioned issues and more careful formulation and testing of relevant hypotheses.

- Another Career Choice for BA Psychology Students**
- I would like to congratulate Pinkus and Korn (August 1973) for their efforts on behalf of the BA (psychology) graduate. My own dual roles in psychology and engineering have given me many occasions to reflect on the vast difference between the utilization of bachelors graduates in these two fields and, following from this, the great differences in attention paid to the undergraduate and his curriculum. I think many more professors in psychology would feel better about their undergraduate teaching and advising if they felt it really had some fairly definite and important purpose. I hope individual faculty, departments, and the APA will ponder this question further.
- I would like to introduce another career direction to this discussion: the engineering psychology/human factors/ergonomics area. Although I currently believe that a master's degree is necessary for adequate entry here, I also believe that delineation of this area is in the spirit of the article's considerations. While at the University of California, Berkeley, and now at the University of Wisconsin, Madison, I have had the occasion to advise a number of BA psychology students who subsequently gained an MS in engineering in the Industrial Engineering Department. While I cannot claim to have any final curriculum suggestions, it is clear to me that an MS in appropriate engineering study can follow the BA in psychology and, more importantly, can build on it, rather than simply consider it largely "wasted time." What can be done, of course, depends largely on what the student did with his BA—a point more closely in tune with the article. Last week I had the singular joy of helping a new junior in psychology plan for a human factors career. It was clear that in his remaining two years he had a number of choices within his BA requirements that could greatly effect his entry into the field. Unfortunately most psychology students do not get advice this early.
- I believe the appropriate MS product in this field is a student who

will occupy the role of a human factors specialist within a broader systems engineering framework. To implement this I advise students to pursue two components in their master's work: (a) sharpen their "applied experimental psychology" skills in the direction of human factors design and research needs and (b) acquire skills in system engineering analysis and design. Our department offers a number of graduate courses in analysis and design that a (properly prepared) BA in psychology is perfectly capable of using.

There are jobs in a great variety of places for such students. I would like to encourage psychology departments and undergraduate students to contact human factors, industrial engineering, or systems engineering specialists and departments to explore this potential.

Certification of School Psychologists

In "Requirements for Certification of School Psychologists," Graff and Clair (August 1973) wrote, "It appears that the profession of school psychology in Canada is either quite limited, or not regulated by provincial departments of education [p. 709]."

I can assure them that school psychology is in a very healthy state at least in some parts of Canada, particularly in Alberta, Quebec, and Ontario. The Calgary Board of Education's Division of Special Educational Services, for example, has a very flourishing school psychology section. The second half of Graff

and Clair's statement is, *dei gratia*, true.

Graff and Clair also implied that Ontario is the only province with certification. This is not the case. I believe each of the 10 provinces now has a certification act. Psychologists are, however, certified as psychologists, not as particular specialists. At least in Alberta, control of specializations is achieved by means of the Ethics Committee of the Psychologists Association of Alberta rather than by specific legislation. It may be of interest to know that of the 335 certified psychologists in the province, about 33% are engaged in school psychology in one form or another. Of another roughly 33% in the universities, several are school psychologists by origin.

At both the University of Calgary and the University of Alberta (Edmonton), there are important training programs at the master's and doctoral levels for school psychologists. In both cases these programs are in the Department of Educational Psychology.

GRAFF, M., & CLAIR, T. N. Requirements for certification of school psychologists: A survey of recent trends. *American Psychologist*, 1973, 28, 704-709.

B. P. FROST
University of Calgary

Editor's note. Another reader (Carole W. Kinder, Follow Through Program, Fairfield County Schools, Winnsboro, South Carolina) has noted that the certification requirements for South Carolina as they appear in the Graff and Clair article are in error (p. 707). South Carolina does require a teaching credential as well as an internship for all three levels of school psychologist. There is also an educational evaluator position which requires 18 hours of special courses, a teaching credential, and an "externship."

On "A Functional Analysis of Depression"

As a practicing behavioral therapist, I found that Ferster (October 1973)

failed to recognize some significant clinical subtleties in his functional analysis of depression. Nonconsideration of these subtleties by therapists is potentially dangerous. For example, Ferster reported that a depressed person "repeatedly tells how badly he feels, cries, talks about suicide, and complains of fatigue and illness [p. 858]." But what about the "smiling depressives" who deny their feelings of pervasive gloom and, after lulling their gullible therapists into a false sense of security, enter the ultimate extinction process via an overdose of some lethal "stimulus"? While Ferster faintly alluded to masked depressions (i.e., those characterized by compulsive, phobic, or ritualistic behaviors), he does not appear to recognize their fundamental clinical significance. Behavioral trainees must be warned to avoid decreasing certain compulsive rituals without recognizing and treating the basic depressive reactions of which they may be a consequence.

It seems that Ferster believes that endogenous depressions (i.e., those due mainly to biochemical, hormonal, and other physiological factors) are necessarily maintained by their functional consequences. This is highly debatable. However, if many of these cases do not receive corrective medication, they may not be available for us to determine the "relation between the [depressed] behavior and the environment that prompts, shapes, and maintains it [p. 861]."

In specifying "decreased frequency" as "the common denominator among depressed persons [p. 861]," Ferster contradicts himself by subsequently addressing the fact that many depressed persons carry on with their day-to-day activities, but nevertheless experience a loss of reinforcer effectiveness in situations that previously had proved highly rewarding. It is circular reasoning simply to ascribe the foregoing phenomenon to inherently unrewarding schedules of reinforcement. The main point about depressed persons is not only the absence of immediate

positive reinforcement but a singular lack of hope of receiving future rewards. The latter consideration led me to develop a therapeutic "positive time projection" technique several years ago (Lazarus, 1968).

Apart from the fact that many depressed persons may not exhibit any decreased frequency in overt activity despite deep subjective levels of misery and feelings of personal unworthiness, there is another error in Ferster's functional formulation. To paraphrase a point that had been underscored by Ferster (1965): Whether a man who becomes less active and more passive is necessarily depressed cannot be determined by observing his behavior alone.

Ferster's penchant for reducing certain complex human behaviors to those of key-pecking pigeons is curiously interspersed with psychodynamic formulations such as "primary and secondary process" (p. 863) and even "repression" (pp. 866, 867). This *paradigm clash* creates the illusion of pseudoscientific respectability for psychoanalysis while breeding a state of confusion worse confounded for behavioral clinicians. All in all, we have yet another instance of a brilliant laboratory scientist overlooking crucial components in the less structured gray world of the clinic and the natural environment "because the tight environment of the experimental testing ground makes it impossible for certain behaviors to occur or for certain observations to be made [Lazarus & Davison, 1971, p. 196]."

Ferster Replies:

I neither intended to make a case for psychoanalysis nor wished to ignore the knowledge of human conduct from that point of view. Apparently, my use of the terms *primary process* and *repression* was found to be distressing. I will postpone to a future paper a substantive discussion of the aspects of human conduct that prompt clinical observers to use these terms. For the present, I will comment on why, as a behaviorist, I pay attention to mentalistic concepts, such as those of Freud and others who followed his lead.

I have never thought of behavior principles as a substitute for knowledge about the content of human activity. Nor have I been able to accept the conclusion that all psychodynamic clinicians ensnared patients into years in treatment without tangible benefit. Clinicians I have known have described their patients to me in sufficiently plain English about overt behavior so that I feel assured that large therapeutic changes were accomplished. I have found that my training as a behaviorist and my attitude as a natural scientist have given me the possibility of crossing the boundary of the clinician's mentalistic language, not by translating it but by using it as an indicator of what the clinician has observed that prompts him to speak as he does. The language and the epistemology of psychodynamic concepts are not to my taste, but I am impelled to deal with them because they are used by many of the clinicians with the most experience with the widest range of behavioral prob-

lems. When I hear a clinician talking about a patient, even mentalistically, my habit is to question him about what he observed firsthand. In most cases, I find the facts and observations quite readily available, particularly when I show an interest in the details of what has gone on between him and his patient.

Although I have done enough clinical work, both individual and group, to make me familiar with the major dimensions of psychopathology and psychotherapy, it is quite correct that as a person trained primarily as an experimental psychologist, I have not met the breadth and variety of problems that would be the case if I were a full-time clinician. Perhaps it is just this combination of point of view that allowed me to break away from a formal topographic view of depression in favor of a functional analysis emphasizing the frequency of generically defined classes of behavior. It is only in this kind of simplification that the analyses I presented have any advantage over the detailed description of the practitioner. Such a theoretical organization helps the reader to notice aspects of the patient's behavior that will guide his intervention. The theory presented in my article dealt with frequency as the dependent variable and the basic behavioral processes as the independent variable. In psychoanalytic theory, the major events are the child's developmental interaction with the parents. Hopefully, the theoretical organization of a functional analysis of behavior will help to make the knowledge of psychodynamic psychology and practical knowledge of depression communicable.

It should seem clear at this point that I did not intend my article to be a guide for beginners to treat depression, like they would use a microtome's vade mecum. I don't believe there is a quick way to learn to treat difficult patients. My hope would be that it would be a guide for acquiring clinical experience more efficiently than from a mentalistic vantage point. I believe that

a beginner has a better chance of identifying the "the smiling depressive" or having some perspective about how to think about drugs and hormones if he understands the functional approach to describing depression than without it. The real danger to effective clinical work is to shut oneself off from information that can assist in the patient's treatments.

A Return to Introspectionism?

Royce (October 1973) documented well the cycle of monism-dualism in the philosophy of man and was accurate in his denunciation of the "official doctrine" of dualism.

Skinner's (1971) straw-man account of "autonomous man" revealed him to be a dyed-in-the-wool dualist. Although he strongly denies the existence of the "fictitious" autonomous man, Skinner advocates that society express its free will by controlling contingencies of reinforcement on a large social scale. But if behavioral determinism is to reign supreme and if Skinner has really been successful in debating to death his free-willing "autonomous man," then from whence comes the human or mystical force to interfere with the determined

natural and social phenomena? "Autonomous man" refuses to die, even at the hands of such an eloquent positivist.

Psychologists might find interesting a new interpretation of quantum mechanics which offers a pluralistic model for monism. This model, developed by Everett (1957) under the academic guidance of Wheeler (1957), includes a noncollapsing state vector for the whole universe. This state vector may be split up into orthogonal vectors, each of which is observed from a mutually exclusive perspective. This splitting into orthogonal vectors reflects a continual splitting of the universe into a multiplicity of mutually unobservable but equally real universes. The splitting is induced primarily by the act of human measurement, although the observer sees only the universe-as-he-sees-it and not the splitting process itself (DeWitt, 1970). For any given time period the observer can be aware of only one of a number of worlds (Cooper & Van Vechten, 1969).

A return to introspectionism? But of course! Psychologists Wundt have it any other way, it seems.

More on Sex and Salary

Cates (October 1973) noted that female psychologists earn less money than male psychologists. While the point is valid and needs to be made, the magnitude of the difference may be deceiving.

Specifically, would the magnitude shown be as large if the variables of age and years of professional experience were held constant? Any data on the point?

THE FREUD/JUNG LETTERS

The Correspondence between
Sigmund Freud and C.G. Jung

Edited by WILLIAM McGUIRE

Translated by RALPH MANHEIM and R.F.C. HULL

"The publishing event of 1974"

—Psychology Today

THE FREUD/JUNG LETTERS

**The Correspondence between
Sigmund Freud and C. G. Jung**

Edited by WILLIAM McGUIRE
Translated by RALPH MANHEIM
and R.F.C. HULL

In April 1906, Sigmund Freud wrote a brief note to C. G. Jung initiating a correspondence that was to record the rise and fall of the close relationship between the founder of psychoanalysis and his chosen heir. This correspondence is now available for the first time, complete except for a few missing letters apparently lost long ago.

"The long-awaited publication of this correspondence is awesome in what it reveals of both men... It belongs in the library of all those who try to remain on intimate terms with the main currents of the intellectual history of our present century." — Dr Donald M. Kaplan, Associate Editor, *American Imago*

"These letters provide indispensable information for understanding the personal and human background to the discoveries of psychoanalysis and analytical psychology. . . . Read sequentially, the letters convey the inexorable quality of tragic drama." — Edward F. Edinger, M.D., *Library Journal*

"A major source for the history of psychoanalysis and of its two most important and interesting practitioners."

Rijksuniversiteit Utrecht

THE NETHERLANDS
(STATE) UNIVERSITY OF UTRECHT
FACULTY OF SOCIAL SCIENCES

Applications are invited for the full-time post of

READER IN SOCIAL PSYCHOLOGY

and in particular the introduction to the subject.

The duties of the successful applicant, who will be attached to the Institute of Social Psychology, will consist of

- the teaching of social psychology to the following categories of students:
- BA in psychology, including propaedeutics;
- students of other faculties reading Social Psychology as a subsidiary subject.

A wide knowledge of the literature in this field is essential.

- the initiating of, and cooperating in, educational innovation within the institute and the subfaculty;
- conducting sociopsychological research in education, and/or conducting research in areas of social-psychology that have still to be developed in the institute.

The successful applicant will be expected to direct the BA courses in the institute.

Those interested in this position, and those acquainted with possible candidates, may write to the Chairman of the Appointment Committee, % Mrs. M. Raaijmakers, Faculty of the Social Sciences, Bijlhouwerstraat 6, Utrecht, The Netherlands, up to three weeks after the appearance of this advertisement.

Applications should be accompanied by a curriculum vitae and a list of publications.

It is expected that the candidate be prepared to learn Dutch.

Further details can be obtained from the faculty office, tel. 030-331123, extension 31, or from the chairman of the Appointment Committee, Prof. Dr. J. M. Rabbie and from Prof. Dr. A. Hazewinkel and Dr. J. Steijnen, Institute of Social Psychology, tel. 030-331211.

**The salary range is £ 7497,00—10762,00 or
Dfl. 50.077,80—71.891,70 per annum.**

It takes more than pilots to keep the Air Force flying.

Like the Air Force Psychologist. Because he helps Air Force personnel understand themselves and their motivations better. Understand others. And understand their role in relationship to the entire Air Force.

As an Air Force Psychologist and Officer, you'll be working and learning with some of the best professional people in your field. As well as experts in other medical fields. Aerospace technology will present exciting, unique areas for you to study and get involved in. Research and experimental facilities are top-notch, too.

But there are nonprofessional reasons for joining the Air Force. Like a good salary...travel opportunities...plus a 30-day paid vacation every year.

Look into the Air Force. There's a lot more to it than meets the eye. For more information fill out the coupon.

Health care at its best.

The Air Force.

SOCIAL PSYCHOLOGY

Issues and Insights/2nd edition

GOODWIN WATSON, *Columbia University*, and DAVID W. JOHNSON, *University of Minnesota*

This edition offers increased emphasis on the application of social psychological knowledge to the solution of current social problems, and will appeal to instructors who seek a current alternative to texts that principally stress theory and research. Approximately half the material in this edition is new. *Instructor's Manual*.

475 pages/1972/paperbound \$7.75

CONTEMPORARY SOCIAL PSYCHOLOGY

Edited by DAVID W. JOHNSON, *University of Minnesota*

The editor seeks to demonstrate that well-validated social psychological theory can be applied effectively to the solution of social problems and improvement of interpersonal relationships. Consisting of introductory essays by the editor and a selection of appropriate articles, the book progresses from a definition of humanistic social psychology to discussions of self-actualizing relationships, and relationships between individuals, organizations and society.

479 pages/1973/paperbound \$6.75

BEHAVIOR DISORDERS

Perspectives and Trends/3rd edition

OHMER MILTON and ROBERT G. WAHLER, *University of Tennessee*

The editors have completed a major revision of this outstanding collection of readings. Divided into three sections, The Medical Model, Situational Influences, and Alteration of Behavior, nineteen articles—sixteen new to this edition—provide students with an overview of current thinking and the results of recent psychosocial research on abnormal behavior.

326 pages/1973/paperbound \$5.75

DIMENSIONS OF PSYCHOLOGY

Introductory Readings

Edited by GALE B. BISHOP, *University of Albuquerque*, and WINFRED F. HILL, *Northwestern University*

The editors have selected forty-four articles especially for their capacity to communicate significant research at a level understandable to most college students. The contributors represent a cross-section of researchers, and the selections include material on such relevant topics as drug abuse, mental health and violence.

480 pages/1972/paperbound \$5.95

THE GREAT PSYCHOLOGISTS

3rd edition

ROBERT I. WATSON, *University of New Hampshire*

Professor Watson reviews the lives and works of the principal architects of today's science of psychology from its origins in the thought of pre-Socratic Greeks. Substantially rewritten for added clarity, the book is now available in paperback.

627 pages/1971/paperbound \$7.50

Lippincott

Division of Higher Education, J.B. Lippincott Company
East Washington Square, Philadelphia, Pa. 19105

NEEDED: Two Innovative Psychologists

We need two psychologists who want to help find better ways to use psychology to solve practical problems in society. These psychologists must be well-qualified in clinical theory and practice.

Life Development Center

One psychologist should have a creative interest in helping develop our new clinic, The Life Development Center, as well as in applying clinical skills as a consultant in organizational settings.

The Life Development Center is concentrating on developing an eclectic psycho-technology which will enable us to help people take positive control of the process of developing their talents for a healthy and rewarding life.

Organizational Consulting

The other psychologist should have interests in applying his clinical skills primarily in organizational consulting. This professional will work in programs which aim to increase organizational effectiveness by improving the mesh of psycho-social forces of the organization with the needs of individuals. Our approach is systemic, based on the assumption that the human factors cannot be treated separately from the organizational systems in which they are embedded.

Applicants must hold a Ph.D. degree, the organizational consultant should be willing to accept substantial travel and both will need to relocate to Greensboro, N.C. Inquiries and resumes should be directed to:

Dr. Richard M. Furr
Farr Associates, Inc.
910 North Elm Street
Greensboro, N. C. 27401
(919) 274-8483

A provocative book of essays on the mind ...
...the "other" mind.

THE NATURE OF HUMAN CONSCIOUSNESS

A Book of Readings

Edited by Robert E. Ornstein

The movement toward an understanding of the intuitive mode of consciousness has inspired a brilliant book of readings—an exciting mix of the *I Ching* and neurophysiological essays on the brain, Sufi literature and linguistic analysis, and much more. Contributors include Charles Tart, Arthur Deikman, William James, Carl Jung, and Roberto Assagioli, along with representatives of the "esoteric" psychologies such as Lama Govinda and Idries Shah. It is an eloquent call to extend the boundaries of scientific inquiry as well as our conception of human capacities. \$15.00

THE VIKING PRESS

625 Madison Avenue, New York, N.Y. 10022

THOUGHT AND FEELING: Cognitive Alteration of Feeling States
edited by Harvey London and Richard E. Nisbett

This book consists of experimental studies that derive from and extend Schachter's theory of emotional states and Heider's attribution theory. The papers deal with a wide variety of topics — for example, aggression, boredom, obesity, the control of pain, delusional systems. Each of the authors takes the theoretical concept of cognition and relates it to research he is currently doing in biofeedback, physiology, social psychology, altered states of consciousness, etc. Thus the book bridges the gap between cognitive theory and the utilization of that theory in the applied research that is being done today, and provides a summary of the present state of cognitive research that will serve as a benchmark for future work on the subject.
164pp. April 1974 \$8.95 cloth

CARDIOVASCULAR PSYCHOPHYSIOLOGY: Current Issues in Response Mechanisms, Biofeedback and Methodology
edited by Paul A. Obrist, A.H. Black, Jasper Brener, and Leo V. DiCara

This book — containing original papers by the leading authorities on the subject — offers the first comprehensive overview of the entire field of cardiovascular psychophysiology. The chapters are varied as to the scope and depth of coverage. Some detail efforts of individual investigators, others are critical overviews of an area, and still others provide some combination of the two. The book ends with a summary by the editors discussing the goals of research and the appropriate strategies for achieving these goals. A remarkable bibliography of nearly 1,000 items provides the first comprehensive guide to the output of research workers in this rapidly growing field.
624 pp. July 1974 \$19.50 cloth

PERSPECTIVES ON SOCIAL POWER
edited by James T. Tedeschi

This book brings together the best work of scholars from many different disciplines in order to organize, develop, evaluate, and interpret scientific theories of social, political and economic power. The contributors illustrate a variety of approaches ranging from ethnographic case studies to mathematically formalized models. The book treats in provocative and creative ways such important problems as the factors that affect the use of power and the nature of response to its use, the linkages that affect the flow of power between individuals and social systems, the consequences of attributions of power by actors and observers, and the implications of trust as an alternative to explicit influence.
440 pp. July 1974 \$14.75 cloth

Also from Aldine:

CONFLICT, POWER AND GAMES: The Experimental Study of Interpersonal Relations
by James T. Tedeschi, Barry A. Schlenker and Thomas V. Bonoma
168 pp. 1973 \$9.50 cloth

THE SOCIAL INFLUENCE PROCESSES
edited by James T. Tedeschi
350 pp. 1972 \$10.75 cloth

The first thing
we did with our
Human Development
series...

Was to find
a good-looking hero.

You see our film strip series deals with real people—
not cartoon characters. And because these real subjects
you are offered a truly exciting look at the first 2 1/2 years
of a child's life.

Episodes of day-to-day life, sequence of language
development, and the child's relationship with
mother and other adults, are presented in a
clear, concise, and informative way. These
episodes of the series are findings of the most
famous authorities, including Piaget, White, Kegan,
and Bower.

Designed for students of education, psychology, home
economics, and the social sciences, Human
Development is far less expensive than movies—and
far less important to overlook.

Human Development - The First 2 1/2 Years

FOR THE HUMANISTIC APPROACH

The World of the Urban Working Class

Marv Fried

Marv Fried describes in detail the daily lives
of the people who lived in Britain's West
End before its demolition in 1958 for the
purpose of urban renewal. Based on extensive
interviewing of the former residents has
been integrated with the findings of a wide
range of literature on working-class commu-
nities in other urban industrial areas to pro-
vide essential knowledge for understanding
the role of the working-class community in
contemporary societies and for anticipating
the impact of social and economic programs
on their lives.

An Introduction to Personality: Research, Theory, and Application, Second Edition, 1974
by Donn Byrne, Purdue University

Not just a revision — but a whole new outlook to show relevance to everyday living and social problems. Dr. Byrne provides your students with a comprehensive introduction to the field of personality — emphasizing current research and past and present theoretical formulations. The second edition retains and updates much of the original material. Also new is coverage of the personality theories of Jung, Freud, and Sullivan. Plus an entirely new emphasis on the situational determinants of behavior. The text presents the two primary approaches to the study of human behavior — individual differences vs. situational determinants. It places students in immediate contact with a broad sampling of current field research and shows the connections between research findings and the way in which such findings can be applied to the world outside the laboratory.

March 1974, 608 pp. \$11.95

Choice and Change

by April O'Connell and Vincent O'Connell,
Santa Fe Community College and University
of Florida, Gainesville

NEW—A humanistic approach to growth and self-actualization. This new text offers a full discussion of personality patterning through the elements that create the emotional self: biological inheritance, cultural determinants, conditioning, and social learning. These elements are analyzed and techniques for integrating personality are discussed. The authors delve into problems facing today's society and provide real life situations for discussion. In addition, the text offers valuable information on dream interpretation and conditioning. Liberally illustrated; includes an annotated bibliography.

**THE PSYCHOLOGY OF
ADULT DEVELOPMENT AND AGING**

surveys what is known
and outlines the unexplored regions
of gerontological psychology

A major product of the American Psychological Association's Task Force on Aging, this rich guide to gerontological research summarizes findings of outstanding leaders in the field and provides a fruitful source of testable hypotheses for investigators in almost every psychological specialty. Editors Carl Eisdorfer and M. Powell Lawton cochaired the APA task force, which was organized in response to a request for representation at the White House Conference on Aging (held November 1971).

The Psychology of Adult Development and Aging amply reaffirms the realization that chronological age is a poor indicator of an individual's cognitive and emotional characteristics. Emphasis is on identification of the contribution of other variables, demonstrating experimental, developmental, and clinical approaches. Topical coverage is unusually broad, ranging from animal and psychophysiological research to problems of education, housing, and transportation. (718 pages. \$11)

To obtain copies, write to the Order Department, American Psychological Association, 1200 17th St., N.W., Washington, D.C. 20036. Prepayment must accompany all orders amounting to less than \$15.

There's no easy way for Charlie Nelson to become Dr. Nelson.

But there is a way to make it somewhat easier. Our way. The Armed Forces Health Professions Scholarship Program. It won't soften the demands of your professors, or those you make upon yourself—but it may free you from those financial problems which, understandably, can put a crimp in your concentration.

If you qualify, our scholarship program will cover the costs of your medical education. More, you'll receive a good monthly allowance all through your schooling.

But what happens after you graduate?

Then, as a health care officer in the military branch of your choice you enter a professional environment that is challenging, stimulating and satisfying.

An environment which keeps you in contact with practically all medical specialties. Which gives you the time to observe and learn before you decide on your specialty. Which may present the opportunity to train in that specialty. And to practice it.

You may also find some of the most advanced medical achievements happening right where you work. Like at the Brooke Army Medical Center in San Antonio, Texas, long noted for its Burn Treatment Center. Or the home of Flight Medicine, the famed Aerospace Medical Division, also in San

Antonio. Or the National Naval Medical Center in Bethesda, Maryland, recognized worldwide for its work in Medical Research.

And if you've read this far, you may be interested in the details. Just send in the coupon and we'll supply them.

The *American Psychologist* is the official publication of the American Psychological Association and, as such, contains archival documents as well as material submitted by authors. Articles should be timely and of broad general interest to psychologists of all scientific and professional persuasions.

Manuscripts must adhere to the instructions on reference citations, preparation of tables and figures, manuscript format, etc., as described in the *Publication Manual of the American Psychological Association*. Manuscripts that do not conform to the style set forth in the *Manual* will be returned for revision. When in doubt about practices of the *Journal*, authors should examine a recent issue.

Articles under consideration or accepted by another periodical of general circulation are not acceptable. Also, articles accepted for publication by this *Journal* may not be reprinted elsewhere without APA permission. Comments should be submitted no later than two months from the date of the issue containing an article on which comment is made in order to ensure timeliness.

Submit manuscripts in triplicate, accompanied by a 100-120-word abstract, to Kenneth B. Little, American Psychological Association, 1200 Seventeenth Street, N.W., Washington, D.C. 20036.

Statements contained in the *American Psychologist* are the personal views of the author and do not constitute APA policy unless so indicated. APA reserves the right to edit all copy and to refuse ads that are not in consonance with the principles of Title VII of the Civil Rights Act of 1964 (Equal Employment Opportunity).

Written permission must be obtained from the APA for copying or reprinting text of more than 500 words, tables, or figures. Address requests to the Permissions Office.

Copyright © 1974 by the American Psychological Association, Inc.

Subscriptions: Subscriptions are available on a calendar-year basis only (January through December). Nonmember rates for 1974: \$12 domestic, \$13 foreign, \$2 single issue. Write to Subscription Section, APA. **Reprints:** Authors may order reprints of their articles from the printer when they receive galley proofs. **Back Issues and Back Volumes:** For information regarding back issues or back volumes write to Order Department, APA. **Microform Editions.** For information regarding microform editions write to any of the following: Johnson Associates, Inc., P.O. Box 1017, Greenwich, Connecticut 06830; University Microfilms, Ann Arbor, Michigan 48106; or Princeton Microfilms, Princeton, New Jersey 08540. **Change of Address.** Send change of address notice and a recent mailing label to the attention of the Subscription Section, APA, 30 days prior to the actual change of address. Undelivered copies resulting from address changes will not be replaced; second-class mail is not forwarded unless subscribers notify the local post office in writing that they will guarantee second-class forwarding postage. Published monthly in one volume, 12 issues, by the American Psychological Association, Inc., 1200 Seventeenth Street, N.W., Washington, D.C. 20036. Printed in the U.S.A. Second-class postage paid at Washington, D.C., and additional mailing offices.

KENNETH D. LITTE 1130 Seventeenth Street, N.W. Washington, D.C. 20036

The American Psychological Association, founded in 1892 and incorporated in 1928, is the major psychological organization in the United States. The purpose of the APA is to advance psychology as a science and as a means of promoting human welfare. It attempts to accomplish these objectives by holding annual meetings, publishing psychological journals, and working toward improved standards for psychological training and service.

In addition to the *American Psychologist*, the Association publishes 13 other journals: *Contemporary Psychology*, *Developmental Psychology*, *Journal of Abnormal Psychology*, *Journal of Applied Psychology*, *Journal of Comparative and Physiological Psychology*, *Journal of Consulting and Clinical Psychology*, *Journal of Counseling Psychology*, *Journal of Educational Psychology*, *Journal of Experimental Psychology*, *Journal of Personality and Social Psychology*, *Professional Psychology*, *Psychological Bulletin*, and *Psychological Review*. The APA also publishes *Psychological Abstracts*, the *APA Member's Monthly Employment Bulletin*, the *Biographical Directory*, the *Convention Program*, and the *Catalog of Selected Documents in Psychology*.

Report of the Executive Officer: 1973

KENNETH R. LITTLER

American Psychological Association

Annually, the Executive Officer is required to report directly to the Council of Representatives and in writing to the members of the APA on the activities of the Central Office, the administrative arm of the Association. The Bylaws are remarkably clear on the nature of those activities, stating merely that there shall be a Central Office with such facilities and functions as Council may assign it, that the Executive Officer shall be the Director of the Central Office, and that the Board of Directors shall supervise him in the execution of his duties. One of the original justifications for a Central Office was the operation of a placement service for returning psychologist veterans, an activity still in operation although with somewhat fewer veterans. However, functions and staff have increased in number since those early days, so much so that this report is limited to highlights.

In contrast to the single brief paragraph on the Central Office in the Bylaws, there is a wealth of detail on the governing structure of APA in that document. This consists of the Council of Representatives as the legislative body, its executive committee, the Board of Directors, and a sizable number of boards and committees reporting through the Board to Council. The system of boards and committees and elected representatives constitutes the decision-making mechanism of the Association. Its general function is to generate and debate policy and to establish the nature of the activities of the Association. It is the task of Council to consider recommendations that have filtered upward through the system for final action or to be informed of informal action that has been taken by the Board of Directors under the authority granted it.

A small number of the governance units are operational committees, that is, committees that have specifically delegated duties which are carried out during the year and reported on only annually to

the Council. Two excellent examples of such committees are the Accreditation Committee and the Committee on Scientific and Professional Ethics and Conduct. Policies governing such operational committees have been hammered out over the three decades of APA's existence in its present form and are embodied as specific directives in various legal documents including the Bylaws and the Rules of Council.
